I have travelled much farther along the road since I wrote my article and realise more than ever the importance of testing specimens taken the last thing at night and the first thing in the morning. This is true both at the preliminary investigation of the patient's urine and while he is under the treatment with alkalis. At the times that a patient is usually seen the alkaline tide is at its height. One must be perfectly certain that alkalis have not been taken in any form before the first tests are made, or one's calculations will be upset; the amount taken may not be enough to clear up the lesions, but enough to bring the pH value of his urine towards the normal figure. When the patient is taking the alkali treatment it is sometimes found that either the night or the morning specimen is still abnormal, in which case an extra dose of the medicine must be given between 4 and 6 o'clock if it is the evening specimen that is abnormal, or the last thing at night if the morning specimen still has a high concentration. There will be little or no improvement in the patient's condition until his urine is normal for the whole of the 24 hours.

The only explanation I can offer to account for the negative results obtained by Dr. Whitfield and others whose patients did not improve on alkalis is that a sufficient amount was not given and that the urine was tested at the height of the alkaline tide, a fallacious value being thus obtained. If the readers

of my article will carry out my technique as advocated and will give alkalis in sufficient quantities to all their patients whose urine has a high acidic value they will be astonished with the results. Like Dr. Barber, I have found that when one starts a patient on alkalis the hydrogen-ion concentration of the urine tends to become higher; for instance, in a case of acne the pH value before treatment was 5.1 and three days later, after having taken large doses of alkalis, it was 4.7. As regards the alkaline tolerance, this is only comparative; it is very much higher than normal, but cannot compare to the enormous tolerance found in true cases of acidosis. In these cases it may take weeks with the patient on ounces of bicarbonate of soda a day before the urine reaches the alkaline side of neutrality, or it may never be reached. As regards cheilopompholyx, all those cases that I have seen since I started my investigations have had a urine with a high pH value. Owing to the intense irritation, however, the lesions are almost invariably scratched, infected with micro-organisms, and the skin sensitised. Thus, unless the patient is seen before this takes place, Dr. Barber is perfectly right in stating that alkalis alone will not cure the condition.

There is one fact that I have never seen mentioned and that is that seborrhœic cases have retraction of their gums, often to a very marked degree. This retraction, unlike that in pyorrhœa, is primarily along the roots of the teeth and not in between. As regards a clinical relapse due to over-treatment with alkalis, I stated that this was a rather rare result. I have only seen one well-marked case, this served as a warning of a possible danger and prevented me over-treating, although several subsequent cases were verging on a relapse; this was prevented by cutting down the treatment.

In my article, under the heading of acne, I stated that local treatment must be energetically carried out. In other words, that I do not consider alkalis alone are sufficient to cure the patient; therefore, Dr. Semon, even if he agrees with me entirely, is perfectly justified in using X rays as an adjunct.

I am, Sir, yours faithfully,

F. CARMINOW DOBLE.

Harley-street, W., Feb. 28th, 1925.

To the Editor of THE LANCET.

SIR.—The correspondence on the acidic value of the urine in skin disorders and other conditions raises points of far-reaching interest and medical importance, and I would like to make one or two comments on it from the standpoint of the general physician.

Twenty-five years ago I had the privilege of being the clinical assistant to the Skin Wards in the Royal Infirmary, under the care of the late Dr. Allan Jamieson, one of the pioneers of dermatology in this country. I formed then the impression, from the general study of the stools and urine, that the general run of skin cases were dependent upon a chronic constitutional disturbance, and required investigation and treatment from a rather wider standpoint than prevailed. I have a vivid recollection of furtive efforts I made to get some stools kept for a general examination, and after seeing them, or one might say coming within range of them, one could not help having some sympathy with the views obviously held by the members of the nursing staff as to the undesirability of trying to combine the work of the general physician with that of a special department. I later made some observations on a few selected cases coming under my own care, and published the results. These appeared to me fully to confirm the impression as to the general origin of these skin affections, this view being, indeed, held by a small number of dermatologists. Since that time there has been much work carried out, more especially by French physicians, emphasising the profound importance, and great value to the patient, of attention

being directed to the subject along these lines, and one therefore welcomes the recent valuable work of Dr. Barber, Dr. Semon, and Dr. Doble on this subject. I believe it will mark an era of advance in our knowledge of the ætiology and treatment of skin disorders of far-reaching importance.

I have read with interest Dr. Whitfield's letter of criticism and appreciate the useful note of caution which it sounds, but in my view—assuming the complete correctness of the facts which he has personally observed—it may be possible to interpret his results in a way which does not seriously invalidate the general conclusions of his brother specialists. I may say I do not completely accept the interpretation of the results of the observations made by Dr. Barber and his colleagues, but it is more important at the moment to emphasise the value of their line of inquiry and the encouraging nature of the therapeutic results they have recorded. I would like rather to touch upon one or two points of a more general kind which have been brought out in their writings.

Dr. Barber has drawn attention to the information which may be obtained from testing the reaction of the saliva in cases of skin disorder. This is an observation which I am satisfied can be usefully extended to many other disorders. His reference to constipation and dyspepsia of the fermentative type as factors of importance in the causation of a seborrhœic state may, I believe, be very usefully extended to other common skin disorders as well as to other departments of general medicine and surgery. I assume that in using the word fermentative he includes dyspepsia arising from putrefactive changes in the bowel. A further point of great value was suggested in Dr. Doble's paper, where he indicated the results of his examination of the urine in cases of so-called nervous disorders. In your issue of Feb. 28th there is a note of unique interest in the letter by the late Sir Clifford Allbutt on Alkalis in Certain Diseases of the Skin in which an interesting clinical fact is recorded, the observation being recorded without explanation, but simply as an empirical result. In this connexion I would like to suggest to our neurological friends that if a consecutive series of, say, 50 to 100 neurological cases were examined from the wider standpoint of medicine heralded in the recent dermatological writings referred to, and the urine, stools, and saliva examined by a slight amplification of the comparatively simple methods described in the published communications in question, data of enormous value would be obtained in regard to nervous disorders, which would have results of far-reaching importance *re* our knowledge of the ætiology of the diseases and add enormously to our skill in their treatment.

I am, Sir, yours faithfully,

CHALMERS WATSON, M.D.

Edinburgh, Feb. 28th, 1925.

To the Editor of THE LANCET.

SIR.—Dr. Barber's letter in your issue of Feb. 21st opens up a line of attack along which the clinical observer may achieve victory over a common and yet too often undefeated malady. But before one can feel convinced that a specific, or even a certain, remedy has been found, the laboratory worker must enter the field and make innumerable painstaking tests as to the degree of acidity of the urine, and also hydrogen-ion concentration measurements. Next must be decided the precise amount of alkali suitable for each case. For, according to the conclusions of the article on hydrogen-ion concentration of the urine, which appeared in your issue of the preceding week, certain skin diseases are cured when the correct degree of alkalinity is reached, but made worse when this exceeds a certain point.

Three questions leap to the mind at once in this connexion: (1) Is not acidity present with many types of toxæmia, and does not such toxæmia exist

often enough with skin diseases to arouse the suspicion that they are causally associated? (2) Surely the acidity of the saliva, at any rate, exists quite commonly in individuals who have not suffered, at any time of life, from any form of seborrhoea, nor, indeed, from any kind of skin disease? (3) Why do many cases of acne and other forms of seborrhoea become cured without receiving any alkaline treatment? To quote a typical case taken at random from my notes:—

Miss R., aged 20, had severe hairfall due to seborrhoea of the scalp; her back was covered with papular acne and had been so for years. The hands were blue and cold, the pulse was always over 100. These latter signs, together with a slight enlargement of the thyroid, gave the clue to the toxæmia existing in her case. A diet of vitamin-containing foods was ordered, farinaceous foods and sweets reduced to a minimum. Parathyroid 1/10 grain and a tablespoonful of paraffin daily were the only internal remedies. Acne bacillus vaccine was given at weekly intervals for the scalp condition. Within a month the pulse had dropped to normal; within two months the acne spots had disappeared, no fresh ones had taken their place, the hair had become steadily less greasy and ceased to fall. Best of all was the progressive improvement in the girl's appearance—the clear complexion, rosy cheeks, the normal pale hands, the absence of thyroid enlargement; from being a tired, uninterested girl, she was transformed into a lively, energetic young woman. No alkalies were given during the course of treatment.

Many similar cases have been seen whose symptoms point to the *Bacillus coli* as the guilty organism. As one of the best methods of dealing with that organism is the administration of large doses of alkalies, it would be of interest to discover whether the colon bacillus were often present in those seborrhoeics who are cured on taking alkalies. In the notes of my pre-war cases these words frequently occur: "Coated tongue, heavy morning sleep," and the best results were obtained by treatment directed to the colon. To-day I recognise that profound sleepiness in the early morning, in otherwise healthy young people, indicates in by far the majority a loaded pelvic colon; in almost all such cases the cæcum is palpable.

I am, Sir, yours faithfully,
AGNES SAVILL.
Devonshire-place, W., Feb. 28th, 1925.

DIAGNOSIS OF APPENDICITIS.

To the Editor of THE LANCET.

SIR,—The correspondence in THE LANCET on this subject brings up once again two—amongst other—important points: (1) the presence of diarrhoea or diarrhoea and vomiting, (2) the presence or absence of "normal temperature" and "normal pulse."

Diarrhoea or diarrhoea and vomiting may be the only symptoms complained of at the commencement of an attack, which eventually turns out to be one of appendicitis, so that careful examination should always be made to exclude the latter at the first visit. As an example of this the following case is typical:—

CASE 1.—On July 8th, 1912, I was called to see R. H., aged 9, who was supposed to be suffering from "summer diarrhoea" with slight vomiting. No pain of abdomen was complained of, but careful examination revealed deep tenderness over the appendix; the latter was removed two hours later and was found to be acutely inflamed.

CASE 2.—In this case, B. L., aged 19, had some slight "stomach-ache" in the afternoon and evening of Nov. 12th, 1913. This was followed by acute pain referred to the umbilicus from 5 A.M. to 7 A.M. on Nov. 13th. I saw the patient at 8.15 A.M., when the latter apologised to me for having me called to see him, protesting that he felt perfectly well. All pain had stopped; there was only very slight tenderness over the appendix. The temperature was 98.4° F. in the axilla; pulse 70. It was well known to me that the patient's ordinary temperature was 97.8° and that his pulse in the ordinary way was never more than 50. The sudden cessation of pain, the slight rise of temperature to the ordinary normal 98.4° and the rise in pulse from 50 to 70 made me confident that the diagnosis was one of perforated

and most probably gangrenous appendix. At operation, two hours later, the appendix was found to be as large as an ordinary sausage, gangrenous throughout, and perforated in two places. The abdomen was closed without drainage. There was rather severe hiccough for 36 hours after the operation, showing that septic absorption had already taken place and that in all probability we had only just got the patient in time. Recovery, except for the hiccough, was uneventful.

In the above case the surgeon was not convinced of the urgency of the case until the rise in frequency of the pulse to 70 was emphasised. Without previous knowledge of the individual patient one may be sadly misled by a "normal temperature" and a "normal pulse."

I am, Sir, yours faithfully,
Streatham, S.W., Feb. 26th, 1925. HARRY E. SMITH.

To the Editor of THE LANCET.

SIR,—Mr. Rendle Short's presentation of the subject of appendicitis in your issues of Jan. 31st and Feb. 7th is as perfect as any I have ever read. I speak as one who for seven years has had to see the patient with appendicitis through his trouble from beginning to convalescence—operation included. But it seems to me that far too much importance is attached to pneumonia—Mr. Rendle Short did not specify lobar pneumonia, as Dr. Knyvett Gordon would seem to imply—in the differential diagnosis. I have attended personally during the last seven years well over 300 cases of pneumonia of all sorts—I am speaking from figures and not memory—and only in one case did the possibility of appendicitis suggest itself to me, and then not very convincingly. This was in a case of central influenzal pneumonia in a boy of 6. These cases present pain referred to the abdomen—a high temperature, and incessant vomiting for the first 24 hours is quite common and not, as Mr. Short states, rather uncommon. Added to this, the chest is silent for days and it may be only a day or two before the crisis that the signs of consolidation are evident, if indeed they become so at all. Moreover, the respiratory distress is not nearly as marked as in lobar pneumonia. This is the type of case where I can conceive difficulties—the ordinary lobar pneumonia with signs at the very onset should not be confused with anything else. It is interesting to note in this connexion that in a similar case of central pneumonia I once had a suspicion of enteric. It would be interesting if some practitioners of wide experience of pneumonia would write their experiences in this direction.

An interesting early sign of appendicitis which I have observed in three cases—first attacks—all within eight hours of onset, is the presence over the appendix region on palpation and auscultation of fine friction sounds, and I operated in two of the cases in the absence of rigidity and fever on the strength of this sign; I was rewarded in all three cases with a definitely reddened appendix and some few ounces of clear serous fluid in the peritoneum. These friction sounds—I think "peritoneal crepitus" would be an apt term for them—I have also noticed in a case of acute cholecystitis (over the gall-bladder) confirmed by operation, and I think they are due to the rubbing of the inflamed peritoneal surfaces on each other. I take it they would disappear when fluid is effused in larger quantity and in a case of any standing adhesions would prevent much peritoneal gliding taking place. They must be, therefore, a very early sign, but I do not pretend to know in what percentage of cases they take place. This may be an old sign—I discovered it quite accidentally and shall be glad to hear if anyone has described it in connexion with appendicitis.

Looking over my last 45 personal cases of acute appendicitis I find that the diagnosis was easy in the majority of cases at least well within 12 hours. One case that it took me 21 hours to diagnose as an abdominal emergency was a pelvic appendix—the

only one of the series. Here there was no fever, tenderness, or rigidity for that period, and when tenderness did appear it was to the left of the middle line. Dysuria and rectal tenderness aroused me (Cope's test was negative), and an incision through the right rectus later disclosed a pelvic abscess. One case, ill for two days before I saw her, passed about 5 oz. of blood per rectum. At operation this was found to be due to a deeply engorged cæcum which had a rotten gangrenous appendix behind it. A drainage-tube was inserted and recovery took place without faecal fistula, which one rather expected.

I am, Sir, yours faithfully,

Aberdare, Feb. 23rd, 1925.

AMBROSE W. OWEN.

"POST-ANÆSTHETIC" VOMITING.

To the Editor of THE LANCET.

SIR,—In view of Dr. Mortimer's article on post-anæsthetic vomiting in THE LANCET of Feb. 14th, perhaps a note of my experience may be of use to others.

Vomiting occurs most frequently with ether anæsthesia, and frequently, though not vomiting, the patient complains that he can taste the anæsthetic for days, or at least until he has had an aperient. My point is that it is the ether vapour which is swallowed rather than that which is inhaled which causes vomiting and retching. This is due to irritation of the gastric mucosa, and consequent secretion of thick mucus in which the ether dissolves, and which remains there until vomited or passed on to the small intestine. While house surgeon at various hospitals I frequently noticed that many patients, especially mouth-breathers, complained of a dry mouth while being anæsthetised, sometimes due perhaps to the injection of atropine they might have had. These patients were apt to moisten their lips and swallow frequently during administration of the anæsthetic, and I perceived gradually that as a rule those who swallowed most were those who vomited later on. I then made a practice of telling the patient to breathe through the nose if possible, and even though the mouth felt dry, on no account to swallow, as he would swallow anæsthetic vapour and increase the risk of being sick. I am pleased to be able to say that in those cases in which the patient refrained from allowing air (and vapour) the vomiting was negligible. In some cases in which the patient had had previous operations with much post-anæsthetic vomiting he remembered that the mouth had been dry and that in consequence he had swallowed frequently; when this was pointed out to him and he refrained from swallowing, there was no vomiting at any subsequent operation.

I am, Sir, yours faithfully,

Ramsgate, Feb. 28th, 1925.

A. J. K. DREW.

TUBERCULIN DISPENSARIES.

To the Editor of THE LANCET.

SIR,—I am one of those doctors who watched and learnt Dr. Camac Wilkinson's method of treating tuberculosis with bi-weekly injections of tuberculin from 1910 onwards, and have myself followed out his teaching carefully with very many good results. From London dispensary work and in sanatoria at Rudgwick, Fritton, and Ockley, we got uniformly good results. And now in 1925 I have been told evidence exists of 50 per cent. of the tuberculin-treated patients being alive *ten years after cessation of treatment*, while as control, only 5 per cent. of the patients who were not so treated were alive, *all* being cases with T.B.

As recently as Feb. 27th a small but important meeting was held in Central London to suggest opening again tuberculin dispensaries. At least eight doctors were present, possibly more. At that meeting it was emphasised that any medical staff should be paid, as it is highly technical work requiring skill

and care, and wants training and practice. But it is work which only requires a couple of hours twice a week regularly and it is of the greatest possible interest. Those of us who have worked at it for years do believe in it—it is only those who do not wait for results who reject it as no good.

In my opinion there are a large number of untouched cases of early tuberculosis who might be entirely saved from disaster by six months' treatment at very little expense and without the patient losing a day's work. Late cases are often improved materially, and in any case the expectoration is minimised and so they become converted into comparatively harmless cases. My object in writing is to say I will give all help I can to any doctor who is anxious to see and learn at 37, Jeffreys-road, Clapham-road, S.W. 4, every Tuesday and Friday from 9-10 A.M.

I am, Sir, yours faithfully,

ANNIE MCCALL,

Feb. 28th, 1925.

Director, Clapham Maternity.

UNILATERAL PHRENIC NERVE PARALYSIS.

To the Editor of THE LANCET.

SIR,—The letter of Mr. Morrision Davies in your issue of Feb. 28th indicated that he has not found symptoms arising after evulsion of the phrenic nerve such as I described in your issue of the 21st, as accompanying pressure paralysis.

Mr. Morrision Davies is probably dealing with tubercle, and as such, his patients are likely to differ from the majority of mine in the following respects: (a) they are younger, or (b) they have had attacks of pleurisy.

As I stated in my paper, the symptoms are least marked in these two classes of individuals—namely, in the young, where thoracic movement is free, and in those in whom the diaphragm on the affected side is anchored by adhesions. This would seem to explain the differences in our experiences.

I am, Sir, yours faithfully,

CHARLTON BRISCOE.

Harley-street, W., March 3rd, 1925.

TINCTURE OF IODINE (PH. FR.).

To the Editor of THE LANCET.

SIR,—In your issue of Feb. 28th the editor of the *Prescriber* points out the difficulty of the absence of a suitable preparation of tr. iodi without potassium iodide. I would like to state that I have for some considerable period used a preparation of iodine with alcohol and glycerine for the intensive iodine treatment on a large number of patients and have had no untoward symptoms, such as iodism, &c., the amount of iodine tolerated being very surprising and the immense benefit derived in arthritic cases has been very assuring. I may add that the formula is to be found in the Extra Pharmacopœia (Martindale), vol. i., p. 1004, under the head of guttæ iodi (Farrer).

I am, Sir, yours faithfully,

CLAUDE ST. AUBYN-FARRER.

Harley-street, W., March 2nd, 1925.

METHYLATED SPIRIT AND ITS SUBSTITUTES.

To the Editor of THE LANCET.

SIR,—With reference to the annotation with this heading published on p. 398 of the issue of THE LANCET for Feb. 21st, we should be glad if you would give publicity to the fact that the Petrohol brand of isopropyl alcohol is imported solely by ourselves. To any of your readers who are interested, we shall be pleased to forward copies of the publications referred to in your article, and for your own information we enclose copies of same.

We are, Sir, yours faithfully,

ANGLO-AMERICAN OIL COMPANY, LIMITED.

Albert-street, Camden Town, N.W. 1, Feb. 23rd, 1925.

Obituary.

GEORGE SIGERSON, M.D. R.U.I., HON.
F.R.C.P. IREL.

Dr. George Sigerson, professor of biology in University College, Dublin, and Senator of the Irish Free State, died at his residence in Clare-street, Merrion-square, Dublin, on Feb. 17th, at a very advanced age. He had received his degree of doctor in medicine as long ago as 1859, and was probably the senior medical practitioner in Ireland. A native of Co. Tyrone, George Sigerson was educated at Cork, Dublin, and Paris, and throughout all his life kept up a close connexion with the medical school of Paris, which he visited almost every year. He was a member of several Parisian scientific societies and of the Scientific Society of Brussels. In his early days he was a pupil of Charcot, of Claude Bernard, and of Duchenne, and he translated Charcot's "Lectures on Diseases of the Nervous System" into English for the Sydenham Society. He also engaged in research work in biology, and his investigations attracted the attention of Darwin and Tyndall. On his return to Dublin Sigerson was, in 1865, appointed professor of botany in the Cecilia-street School of Medicine. Subsequently he became professor of biology in the school of University College and retained that professorship up to his death. He also engaged in private practice as a physician, chiefly concerning himself with nervous affections. He was for a time examiner in psychological medicine and diseases of the nervous system in the Royal University of Ireland.

It was, however, outside the field of medicine that Sigerson earned most distinction. He was an earnest student of the history and literature of Ireland, and translated many of the ancient Gaelic poems into English verse. It is only within the past few months that he published a work on which he had been engaged for years, "The Easter Song of Sedulius." He also wrote an authoritative work on Land Tenures and a book on Political Prisoners. He was a member of Earl Spencer's Commission on Prisons, and was responsible for many improvements in the treatment of prisoners which followed on the report of that Commission.

In 1918 the Royal College of Physicians of Ireland conferred its honorary Fellowship on Dr. Sigerson as a mark of respect for his scholarship. In 1922 he was nominated a member of the first Senate of the Irish Free State, and at the first meeting of the Senate, pending the election of officers, he presided. A man of wide learning in science and literature, with a keen appreciation of the arts, a brilliant conversationalist, Dr. Sigerson was loved for his personality as greatly as he was respected for his scholarship.

REGINALD ARTHUR MORRELL, M.R.C.S.,
L.R.C.P. LOND.

By the death of Reginald Arthur Morrell, honorary radiologist to the Sheffield Royal Hospital, which occurred with tragic suddenness on Feb. 19th, the medical profession of Sheffield and district loses a valued member, and the subject of radiology a promising and enthusiastic worker. Dr. Morrell was at work when he suddenly collapsed and died within an hour from a pontine hæmorrhage; his death came as a great shock to his friends, who were quite unaware of any impairment in his health.

Morrell was born at Pangbourne, Berks, in 1883, and received his early education at Bradfield College. After spending three years at the electrical school of engineering, Kensington, he entered St. Thomas's Hospital Medical School and took the Conjoint Diploma in 1908. He originally intended to practise as an ophthalmic surgeon, and held several hospital appointments in that specialty, on which he contributed papers to *The Lancet* and the *British Medical Journal*, but he became impressed with the possibilities

which radiology offered and determined to take up this branch of medicine. During the war he became attached to the Third South General Hospital as radiologist, with the rank of captain in the R.A.M.C., and later was medical officer in charge of the Physiotherapy Department of Headington Orthopædic Hospital under the Ministry of Pensions. After an assistantship in the X ray department at the Radcliffe Infirmary, Oxford, he was appointed radiologist to the Sheffield Royal Hospital, where he soon proved himself not only a master of technique, but also an able organiser. During his brief tenure of the post the amount of work carried out by his department increased to a remarkable extent. He was a man of great energy, and in addition to a large and growing private clientèle he acted as radiologist to the Chesterfield Royal Hospital, to the City of Sheffield King Edward VII. Memorial Hospital, and as lecturer on radiology in the University of Sheffield. He found time, however, to contribute regularly to the medical press. In 1922 he published in our columns an introductory lecture delivered to the senior medical students of Sheffield University, on Radiology: its Use and Abuse. In it he emphasised the exacting nature of radiology in the service of medicine, pointing out that the radiologist must be a physicist of no mean order as well as an expert biophysicist and a medical man. During recent months he had become deeply interested in violet-ray work, and at the time of his death was engaged in making investigations in this subject.

A colleague writes of him: "He was a man of high ideals, deeply interested in the proper guidance and training of young men. His death leaves a gap amongst both students and staff which will be difficult to fill. Had he lived there is little doubt that he would have taken a high position as a radiologist. At a time when one hears much of the dangers to health which attend workers in this specialty it is assuring to know that Morrell's untimely end could in no way be attributed to that cause."

RICHARD WILLIAMS, M.R.C.S. ENG.,
L.R.C.P. EDIN., L.R.F.P.S. GLASG.,

CONSULTING SURGEON, LIVERPOOL EYE AND EAR INFIRMARY.

Richard Williams, who died at his residence, Pen-Bre, Bangor, recently, in his eighty-first year, obtained his first qualification in Glasgow more than 54 years ago, after which he studied ophthalmology in London and Paris, and held various local hospital appointments in that specialism. In 1873 he became ophthalmic surgeon to the Liverpool Royal Southern Hospital and later surgeon to the Eye and Ear Infirmary, while he also held the appointment of ophthalmic surgeon at the Albert Edward Infirmary, Wigan. He left Liverpool in 1910 after 37 years of steady ophthalmological work, but continued to practise as an ophthalmic surgeon at Bangor until a few months before his death. During the most active part of his career he was a Vice-President of the Ophthalmological Society of the United Kingdom and of the Liverpool Medical Institution, President of the Wigan Medical Society, and a Justice of the Peace for Liverpool.

A friend and colleague writes: "Richard Williams was a man of striking and unusual characteristics, the type of man who has many devoted friends but is sometimes misunderstood by mere acquaintances. He had an original and logical mind, was more of a thinker than a reader, and had a keen eye for essentials. He was a fine operator, high-strung, sensitive, but full of initiative and courage. His ingenuity is shown by the following examples: An eye speculum with eyelash guards; iridectomy scissors for use with the right hand on the left eye; a particularly handy cotton-wool holder; the treatment of conical cornea by the corneal cautery; a method of muscle advancement by a single circular stitch (this operation was usually done in seven or eight minutes under cocaine and was invariably successful); the vertical radial corneal incision in hypopyon ulcer, instead of the

better known Saemisch transverse section; the double iridectomy for incarceration of the iris in a corneal or limbal scar, performed by puncture and counter puncture with a Graefe knife; an excellent but little known operation for ectropion without excision of tissue. But to judge of his resource and inventiveness one had to see Williams at work. Every case was treated entirely on its own necessities and almost without reference to established custom, and this was especially true of plastic operations about the lids and conjunctiva—the greater the deformity the more Williams was pleased and the better seemed the result. Williams was extremely modest and could with great difficulty be induced to publish his methods, so that much of his original work was and is still known to a few colleagues only."

THE BATEMAN APPEAL.

As was explained in THE LANCET last week, it has been felt that material assistance ought to be offered to Dr. Bateman to meet the legal expenses of his recent successful appeal against conviction and to make good the deficiency in his professional income. Accordingly, the Bateman Fund has been opened and remittances should be forwarded to the Manager of THE LANCET, 423, Strand, W.C. 2, and made payable to the "Bateman Fund Account."

We have received:—

H. E. Hall to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS.

Maj. M. D. Ahern is secd. for serv. under the Colonial Office.

Capt. D. W. M. MacKenzie is secd. for duty with Sudan Defence Force.

The undermentioned to be Lts. (on prob.): T. A. J. M. Dodd, R. A. Bennett, Lt. W. D. Speedy (Res. of Off., R.A.), J. N. Atkinson, W. A. D. Drummond, J. D. Corner, W. H. Carter, J. G. E. Vachell, and J. T. Smyth.

The undermentioned Lts. are confirmed in their rank: K. Fletcher-Barrett, C. W. Greenway, A. E. Campbell, and G. C. Phipps.

ARMY RESERVE OF OFFICERS.

Lt.-Col. A. R. O'Flaherty, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

ROYAL AIR FORCE.

G. J. Griffiths is granted a short service commission as a Flying Officer, for three years on the active list.

Medical News.

UNIVERSITY OF LONDON.—A meeting of the Senate was held on Feb. 25th, Prof. E. A. Gardner, the Vice-Chancellor, being in the chair. Dr. J. H. Dible was appointed to the University chair of Pathology tenable at the London School of Medicine for Women. Dr. Dible had a distinguished career at the University of Glasgow, where he obtained the M.B., Ch.B. degrees with honours in 1912, gaining distinctions in zoology, materia medica and therapeutics, midwifery, and surgery. In 1913 he was appointed demonstrator in pathology in the University of Sheffield. In August, 1914, he joined the R.A.M.C., and in 1915 was appointed pathologist to No. 1 General Hospital, B.E.F., and after six months took command of No. 7 Mobile Laboratory until the end of the war. In 1919 he was appointed lecturer in pathology in the University of Manchester and assistant pathologist to the Manchester Royal Infirmary, and in 1921 lecturer in bacteriology and senior assistant in the department. He is the author of numerous publications in scientific medical journals.—The title of Emeritus Professor of Hygiene in the University was conferred on Prof. H. R. Kenwood, who held the Chadwick chair of Hygiene at University College from 1904 to 1924.—The title of Emeritus Professor of Medicine at University College was conferred on Sir John Rose Bradford, F.R.S., who occupied at that College the chair of Materia Medica, Pharmacology, and Therapeutics from 1895 to 1903, and the chair of Medicine and Clinical Medicine from 1899 to 1907.—The School of Pharmacy of the Pharmaceutical Society of Great Britain has been admitted as a school of the University in the Faculty of Medicine (in pharmacy only) for a period of five years as from Jan. 1st, 1925.

The following doctorates have been conferred:—D.Sc. in Biochemistry: Mr. Robert Robison; D.Sc. in Chemistry: Mr. G. R. Clemo; D.Sc. in Physics: Mr. Frederick Simeon.—The following were appointed Fellows of King's College: Prof. Edward Barclay-Smith, Prof. Owen Willans Richardson, F.R.S., and Sir John Charlton Briscoe.

University of London, University College.—The annual report of the College committee for the year ending Feb. 28th, 1925, has just been issued, and indicates a year of considerable activity. During the session 1923-24 the total number of students enrolled was 2835. From European countries there were 177 students: Switzerland 35, France 27, Holland and Russia each 22, Denmark and Germany each 9, Norway and Sweden each 6; 43 students came from the United States of America (17 undergraduate, 24 research, and 2 vacation course). From other countries, the largest—36—came from Japan; of these 8 were doing research work. The College has for many years taken an active part in promoting adult education by providing public lectures that are open without fee. Over 7000 persons attended these lectures during the session 1923-24, the approximate aggregate number of attendances being 12,180. The financial statement shows on the maintenance account a total expenditure of £176,994 and income of £168,943, leaving a deficit of £8051. This deficit is mainly accounted for in the very heavy expenses incurred in the maintenance of the new buildings and in the rating of these buildings. It is also partly accounted for in the slight decline in the number of students in the professional faculties in which fluctuation is bound to take place from time to time according to the financial position prevailing in the country. Steps are being taken to prevent a recurrence of the deficit, and hope is expressed that the University Grants Committee may be able to increase their grant in view of the large donations received by the College through the Rockefeller Trust and other bodies for the erection and equipment of the new buildings. During the year the Ramsay Memorial Laboratory of Chemical Engineering was opened by Prince Arthur of Connaught and is now in full working order. There is a satisfactory list of benefactions and donations, showing that the old students and friends of the College are still active in giving it support.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The nineteenth meeting of the Commission was held at the Home Office, Whitehall, on Feb. 26th, with Sir Andrew Duncan, and later Lord Lawrence of Kingsgate in the chair. The Public Dental Service Association of Great Britain, Ltd., represented by Mr. T. Clifford Wing, L.D.S., Colonel H. C. Howkins, L.D.S., Mr. A. H. Condry, and Mr. P. I. Wigoder, L.D.S., gave evidence on the question of making dental treatment a universal benefit under the Health Insurance Act, and the scope, administration, and cost of such a benefit. Mr. Benjamin Broadbent, J.P., of Huddersfield, submitted proposals for revising and extending maternity benefit. Evidence was given on behalf of the

United Women's Insurance Society by the Lady Emmott, J.P., and Mr. Alban Gordon relating to the general work of the society and in particular to their scheme of dental benefit. Thereafter the National Amalgamated Approved Society, represented by Sir T. Neill, J.P., Mr. Farmer, and Mr. Pike, was heard on the constitution, operations, and finances of that society. The Commission announce that proof copies of the oral evidence and the relative statements submitted at the meeting of Feb. 12th are now on sale at H.M. Stationery Office. (2s. 3d.)

"POTATO WEEKS" AT NOTTINGHAM.—The third annual series of "potato, fruit, and vegetable weeks" in aid of Nottingham General Hospital have brought donations in kind to the value of £500, in addition to £190 in cash.

METROPOLITAN HOSPITAL.—The Lord Mayor Metropolitan Hospital Flag Day Appeal will be held on March 17th. It is hoped to raise a part of the £50,000 required to build the nurses' home and to extend the casualty department of the hospital at Kingsland-road, London, E.

SOCIETY FOR THE STUDY OF INEBRIETY.—The annual meeting of this society will be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W., on Tuesday, April 21st, at 4 P.M., when Dr. Courtenay C. Weeks will open a discussion on Alcohol in Medical and Surgical Practice.

ST. MARYLEBONE HOSPITAL LEAGUE.—Since this league was formed 15 months ago to increase the contributions to hospitals from business houses, £7137 has been collected, as compared with a former average of £1500. The employees' section, which numbers 1900 members, is increasing at the rate of nearly 100 a week.

FRENCH POST-GRADUATE COURSE IN TUBERCULOSIS.—An Easter course of six lectures on Osteo-articular and Glandular Tuberculosis will be given by Dr. E. Sorrel, surgeon to the hospitals of Paris, at the Maritime Hospital at Berck (Pas-de-Calais) from April 6th to 11th. The lectures will be supplemented by demonstrations of methods of examination of patients, treatment, and laboratory technique. Full information may be obtained from Dr. Delahaye, at the Maritime Hospital.

ROYAL INSTITUTION.—On Tuesday, March 10th, at 5.15 P.M., Prof. E. N. da C. Andrade will begin a course of two lectures at the Royal Institution on the Evolution of the Scientific Instrument, and on Thursday, March 12th, Dr. Leonard Hill will deliver the first of two lectures on the Biological Action of Light. The Friday evening discourse on March 13th will be delivered by Prof. Gilbert Murray on the Beginnings of the Science of Language, and on March 20th by Prof. J. W. McBain on Soaps and the Theory of Colloids.

BELGRAVE HOSPITAL FOR SICK CHILDREN.—An offer has been made of £10,000 towards the £30,000 required for the completion of the hospital, the provision of a new X ray department, and accommodation for the nursing staff, on condition that a similar amount is raised in 10 donations of £1000 or 20 of £500 each. At present the nurses live, some in the hospital, and others in two outside houses, one of which is some distance away.

AMERICAN HEART ASSOCIATION.—The first annual meeting of this association was held at the Academy of Medicine, New York, U.S.A., on Feb. 2nd. Dr. Lewis A. Conner, the President, reviewed briefly the progress of the development of the association and commented on the need for such an organisation and the widespread interest which its formation had developed. Dr. Haven Emerson, chairman of the Committee on Membership, described the methods employed to reach all parts of the United States and Canada; regional agents covering one or more States have been appointed, and already 37 States are represented in the membership of the association. It was decided to employ one or more workers with a knowledge of the most recent and approved methods for the prevention of heart disease, and for the organised care of cardiac patients; these workers will be sent to different sections of the country to encourage the establishment of new centres, demonstrate the methods found to be effective, and aid in solving local problems as they arise. At a meeting of the board of directors immediately following the annual meeting, the following officers were elected: Dr. Lewis A. Conner, President; Dr. James B. Herrick, Vice-President; Dr. Robert H. Halsey, Secretary; Dr. Paul D. White, Treasurer; Miss M. L. Woughter, Acting Executive Secretary. The central offices of the society are at 370, Seventh-avenue, New York.

A HOSPITAL FOR WEMBLEY.—A hospital is to be erected at Wembley at a cost of £12,500, nearly half of which has already been raised. A site has also been given.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—A meeting will be held at the Elizabeth Garrett Anderson Hospital on March 10th at 8.15 P.M., when Dr. Dorothy Hare will read a paper on the Value of the Electrocardiograph to the Physician and Surgeon.

SOCIETY FOR CONSTRUCTIVE BIRTH CONTROL AND RACIAL PROGRESS.—A special meeting of this society will be held on March 15th, at 3 o'clock, at the Criterion Theatre, Piccadilly-circus, London, W., to discuss Why Doctors Disagree About Birth Control. The chair will be taken by Sir John Cockburn, M.D., and the meeting will be addressed by Dr. H. Maxwell Telling, Dr. Jane L. Hawthorne, Mrs. Marie Stopes, D.Sc., Ph.D., and others.

HOSPITAL ACCOMMODATION IN NORTH-WEST MIDDLESEX.—The Ministry of Health has sanctioned the raising by the Hendon Board of Guardians of a loan of £134,000 for the erection of a hospital to take the place of the infirmary which was built about 80 years ago.—Pinner and Northwood have decided to join forces for the provision of a permanent cottage hospital in the latter parish. The present hospital is housed in a temporary building.

BRITISH ORTHOPÆDIC ASSOCIATION.—The first award of the Sir Robert Jones Medal and British Orthopædic Association Prize of £50 has been made to Mr. G. Perkins, F.R.C.S., assistant surgeon at the Royal National Orthopædic Hospital, for his essay on the Diagnosis, Treatment, and End-results of Tuberculous Disease of the Hip-joint. The subject of the essay for 1925 is the Classification and Differential Diagnosis of the Different Forms of Arthritis. Particulars may be obtained from the hon. secretary of the Association, 1A, Portland-place, London, W. 1.

ECCLES HOTEL ESTABLISHMENT, BANTRY BAY.—On March 1st-2nd a large medical party visited the Eccles Hotel Establishment, Glengariff. Situated on Bantry Bay in the extreme west of Ireland, it has a long reputation as a climatic station, and recently peat- and sun- and light-baths have been employed in the establishment with success. It is proposed to develop these and other methods of physical treatment on the expressed medical opinion that the climate, together with suitable medical facilities, will be of benefit in convalescence from illness or operation, in many neuros-thenic cases, and in certain forms of rheumatism. Glengariff occupies a very sheltered position at the head of the bay, intersected by headlands, and containing many rocky islands where semi-tropical vegetation flourishes. Fuchsia hedges, eucalyptus, hydrangea, and myrtle attest the mildness of the climate. The party from London were met by Sir William Thompson, President of the Royal College of Physicians of Ireland, and various well-known Irish physicians.

VENEREAL DISEASE: Deputation to the Minister of Health.—On March 3rd the Minister of Health, supported by the chief medical advisor, the secretary of the department, and other technical advisors, received a joint deputation from the National Council for Combating Venereal Diseases and the Society for the Prevention of Venereal Disease. In the absence of Lord Trevethin, President of the National Council for Combating Venereal Diseases, the joint deputation was introduced by Sir Auckland Geddes, President of the Society for the Prevention of Venereal Disease, acting on behalf of both societies. Sir Auckland Geddes stated the case on the lines agreed by the joint conference of the two societies, and supported the recommendation contained in Clause 14 of the Trevethin report: "That the law should be altered so as to permit properly qualified chemists to sell ad hoc disinfectants, provided such disinfectants are sold in a form approved and with instructions for use approved by some competent authority." Sir Auckland Geddes further urged on behalf of the deputation that this competent authority preferably should be the Ministry of Health, otherwise the Medical Research Council or a commission of experts. In reply, Mr. Neville Chamberlain thanked the deputation for attending and promised to consider carefully the suggestions which had been made. He would communicate the result of his further consideration of these suggestions to the two societies as soon as possible. The members of the joint deputation were as follows:—National Council for Combating Venereal Diseases: Mr. L. Bowden, Mr. D. Bramah, Mrs. Ogilvie Gordon, Prof. Kenwood, Dr. D. Lees, Mrs. Neville-Rolfe, and Mr. E. B. Turner. Society for the Prevention of Venereal Disease: Sir Auckland Geddes, Dr. Jane Lorimer Hawthorne, Dr. R. A. Lyster, Dr. Mearns Fraser, Mr. Basil Peto, M.P., Mr. Frank Souter, and Mr. Wansey Bayly.

Parliamentary Intelligence.

HOUSE OF COMMONS.

MONDAY, FEB. 23RD.

The Production of Certified Milk.

Mr. HURD asked the Minister of Agriculture what was the number of producers of certified milk as compared with a year ago, and whether, in the interests of public health, he would recommend that the licence fee for such producers be made purely formal so as to encourage farmers to produce this milk.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: The number of producers of certified milk at the present time is 74. I cannot give the number for this date last year, but the numbers at Dec. 31st, 1923, and Dec. 31st, 1924, were 55 and 71 respectively. The licence fees have been settled on a basis estimated to cover the special expenses of the Ministry of Health in respect of inspection and bacteriological examinations, and my right hon. friend does not think that he can recommend any reduction.

WEDNESDAY, FEB. 25TH.

Nursing Homes Registration.

Mr. G. B. HURST, in asking leave to introduce under the Ten-Minute Rule a Bill "to provide for the registration and inspection of nursing homes," said it was a measure which could not be regarded as being of a controversial character, and among its backers were members of all parties in the House. At present the term "nursing home" had no meaning whatever. Any person, however unqualified, could call his or her institution, however ill-run or managed, a nursing home, however unskilled or untrained the nurses might be and however extortionate the charges. The prevalence of these bogus institutions dragged down the prestige of great and deserving institutions, and the expense of such institutions was a drain on public resources. The intention was to provide for the registration and inspection of nursing homes, so that no institution could be carried on as a nursing home which was not worthy of the title. Under the Bill no institution would be entitled to be called a nursing home if it was carried on by unqualified or unsuitable persons or if the nursing or domestic staff was ill-accommodated and the ventilation bad, or the lighting or warming inadequate. Those having charge of the management would have to be State-registered nurses after Jan. 1st, 1930. Nothing in the Bill was intended to preclude anyone having no connexion with the nursing profession from being registered, but the matron or person in charge must be a fully qualified person. Persons refused registration could appeal to the Minister of Health and he could appoint a referee to deal with the complaint. The question of proprietorship was unaffected, and so far as the details were concerned the promoters were most anxious to meet everybody interested, so that the measure might be definitely regarded as uncontroversial. Although the Bill had been drafted by the College of Nursing, it was not intended to help any section, but to help all nurses. He hoped that the Ministry of Health would do what it could for the Bill. The motion for leave to introduce the Bill was agreed to and the measure was brought in and read a first time.

Diabetes Treatment in Scotland.

On the motion for the second reading of the Public Health (Scotland) Amendment Bill,

Sir J. GILMOUR (Secretary for Scotland) explained that it was exactly the same measure as that which the House discussed last year, and which, after passing through the House of Commons, was given a second reading in the House of Lords. It empowered the public health authorities in Scotland to provide insulin to persons suffering from diabetes who required assistance in obtaining the treatment. It was a matter of some urgency, because since the early part of 1924 certain local authorities had been, in fact, providing insulin, and this Bill was for the purpose of regularising the position. The Bill was confined to diabetes.

Mr. J. STEWART (who was Under Secretary of Health for Scotland in the Labour Government) said that he thought it was very creditable to the Government that they were anxious to give effect to the promise made last year. Everyone who knew what the treatment of diabetes by insulin meant would realise that this was a scheme which ought to be hastened. But there were many diseases of a somewhat similar nature about the cure of which nothing was known at present. The Labour Party thought that provision should be made for the treatment of other diseases if occasion arose without the need for passing a separate Bill. Under the Bill of last year it was provided that the measure could be applied to other diseases besides diabetes by an Order in Council laid on the Table and passed by both

Houses of Parliament, and he urged that provision should be re-inserted in the present Bill.

Several other Labour Members having supported Mr. Stewart,

Sir J. GILMOUR said that he could give no assurance that if the Chairman of the Scottish Grand Committee would allow an amendment to be moved restoring the former provision that the Government would be willing to accept it.

Labour Members continued to protest, and Sir J. Gilmour remarked that if the Opposition preferred to lose the Bill it was for them to decide.

Mr. Buchanan was still speaking when at 8.15 P.M., under the rules of the Houses, the debate was adjourned in order to allow a private Bill to be discussed.

Inoculation of Naval Ratings.

Mr. ROBERT YOUNG asked the First Lord of the Admiralty how many naval ratings were inoculated against enteric fever during the past six months; how many refused to be inoculated; whether any naval ratings were refused leave for declining to be inoculated; and, if so, what ranks they belonged to and the dates of refusal of leave.—Mr. J. C. DAVIDSON (Parliamentary Secretary to the Admiralty) replied: The statistics asked for would entail reference to all H.M. ships and establishments in different parts of the world and involve much time and labour. The regulations on the subject are given in Sections 10 and 11 of Article 1316 of the King's Regulations and Admiralty Instructions which reads as follows:—

10. No punishment or penalty is to be incurred for declining vaccination or revaccination on conscientious or other grounds, but every precaution is to be taken to prevent objectors becoming a danger to the Service. They are not to land in ports where there may be any danger of contracting small-pox, and while the ship is lying at such ports they are to be inspected daily by the medical officer. The fact that a man has refused vaccination or revaccination is to be noted on his Service certificate, and in no circumstances is he to be allowed to re-engage or to be enrolled in the Royal Fleet Reserve (see Article 830, Clause 9).

11. When circumstances arise which render it advisable to inoculate officers and men against enteric fever, cholera, or any other infectious diseases, voluntary inoculation can only be performed. The provisions of Clause 10 are to apply to persons objecting to such inoculation on conscientious or other grounds.

Cost of Maintenance in Asylums and Sanatoriums.

Mr. HANNON asked the Minister of Health the average annual cost, including administration per individual, of maintaining patients in sanatoriums, county and borough asylums, and institutions belonging to Poor-law authorities.—Mr. NEVILLE CHAMBERLAIN replied: The average gross cost per inmate for the year 1923-24 is as follows: Sanatoriums, £136; county and borough lunatic asylums, £75 10s.; and Poor-law institutions, £63 10s. It will be understood that the figure given for Poor-law institutions covers all persons in receipt of institutional relief and not merely sick persons.

THURSDAY, FEB. 26TH.

Mortality Among Ex-Service Men.

Mr. GROVES asked the Minister of Pensions whether he had statistics to show whether the disabilities from which ex-Service men suffered had progressively decreased or increased; and the degree of mortality among those ex-Service men who received pensions in 1920, 1921, 1922, 1923, and 1924.—Major TRYON replied: The statistics of my department taken over a term of years show that in the great majority of cases the ailments or injuries occasioned by war service have either reached a stable condition or have materially improved, though necessarily a proportion of the cases have deteriorated. The mortality among men on the pension list in each of the six years from 1919 to 1924 has been 13.5, 11.6, 12, 14, 12 and 13.5 per 1000 respectively.

Medical Referees.

Mr. THOMAS WILLIAMS asked the Home Secretary if he was aware that in certain cases the medical referee under the Workmen's Compensation Act had been known to be almost a permanent representative of employers in compensation disputes; and would he take steps so that in future all medical referees should be independent of either employers or employees.—Mr. LOCKER-LAMPSON replied: I know of no such cases among the medical referees at present appointed under the Act. It is a condition of the appointment of a medical referee that he shall hold no permanent employment either on the employers' or on the workers' side, and the medical referees are enjoined that in their private practice they should as far as possible avoid cases which are likely to come before them in their official capacity. It has not been found practicable to impose any further restrictions on them.

Unhealthy School-buildings.

Mr. ROBERT YOUNG asked the President of the Board of Education whether he could say when the last survey of

school-buildings was taken; how many education authorities had been notified of the unfit and unhygienic condition of their schools; and what was the number of such schools throughout the country.—The DUCHESS OF ATHOLL (Parliamentary Secretary to the Board of Education) replied: A survey was made last year of the worst public elementary school premises in the areas of the London County Council, the county boroughs, and the boroughs and urban districts in England, which are local education authorities for elementary education. As a result, letters have been addressed to 165 authorities (out of 239), and the number of schools or departments mentioned is 807 (out of 5760). This figure includes not only schools which in the opinion of the Board are altogether unsuitable, but also schools which are structurally unsuitable in part or for their present numbers in varying degrees. A similar survey is in progress in the areas of the county councils in England (apart from London) and it is hoped that the results of the survey of the areas of all local authorities in Wales will shortly be available.

Government Medical Staff.

Lieut.-Colonel HORLICK asked the Minister of Health what was the total cost of the medical staff of the Local Government Board in 1914 and 1918, and of the increased medical staff of the Ministry of Health in 1919, 1923, and for the current year; and how many new medical officers had been appointed in the last 12 months.—Mr. NEVILLE CHAMBERLAIN replied: The total cost of the medical staff of the Local Government Board for salaries and travelling and subsistence expenses was £30,420 in 1914–15, and in 1918–19, including bonus, £35,743. The medical staff of the Ministry of Health cost £55,985 in 1919–20, £121,454 in 1923–24; the estimated cost for the current financial year is £122,910. My hon. friend is no doubt aware that the functions of the Ministry of Health include not only those of the Local Government Board, but also of the National Health Insurance Commissions for England and Wales. The figures for 1923–24 and the current financial year include the salaries and expenses of the regional medical officers; approximately four-fifths of the total cost of this service is recovered out of National Health Insurance funds. Three new medical officers have been appointed in the last 12 months to fill vacancies in existing posts.

Antenatal Clinics.

Mr. WINDSOR asked the Minister of Health whether he proposed, in view of the present rate of maternal mortality, to call the attention of local authorities to the importance of establishing effective antenatal clinics and of making adequate provision for the care of women about to become mothers.—Mr. NEVILLE CHAMBERLAIN replied: A circular was issued by my department on June 30th calling the attention of local authorities to the importance of these and other measures for reducing the maternal mortality-rate.

Infant Mortality in Bombay.

Mr. JOHNSTON asked the Under-Secretary of State for India whether he was in a position to give the official figures on the infant mortality in Bombay during the year 1921.—Earl WINTERTON replied: According to the reports of the health officer of the Bombay Municipality the infant mortality in Bombay City was 667 per 1000 births in 1921, 403 per 1000 in 1922, 411 per 1000 in 1923, and 419 per 1000 in 1924. Examining in 1922 the vital statistics from the beginning of the century the health officer remarked that the fluctuations in infant mortality, which corresponded in time and direction with those of the general death-rate, were indirectly or directly due to plague in the first decade of the century and to influenza in 1918–21.

FRIDAY, FEB. 27TH.

Unqualified Dental Dressers.

Lieut.-Colonel MASON asked the Minister of Health how long the unqualified dental dressers, employed under the Ministry of Education in Derbyshire and Shropshire, would be permitted to continue in practice.—Mr. NEVILLE CHAMBERLAIN replied: The conditions under which dental dressers may be employed in the school dental service have been formulated in a circular issued by the Board of Education after consultation between the Dental Board and the Ministry of Health. In order to allow time for the arrangements in Derbyshire and Shropshire to be reorganised in conformity with the new conditions, permission was granted to the local education authorities of these counties to continue the employment of their existing dental dressers without modification up to the end of the present year.

MONDAY, MARCH 2ND.

Pensions Medical Officers and Overseas War Service.

Colonel Sir ARTHUR HOLBROOK asked the Minister of Pensions what were the special qualifications, medical or otherwise, of each of the undernamed officers without overseas service, which rendered their retention in the service

of the Ministry, in the interests of the pensioner, more desirable than that of the officers with overseas service and in some cases with a war disability whose full-time services were about to be terminated: Dr. A. C. Pickett, Bristol (no overseas service), Dr. A. Williams, Brighton (no service during the war), Dr. J. D. Allen, Bath, and Dr. T. Sheedy, Ministry headquarters, London; whether he was aware that one of their number only obtained his medical qualifications in the year 1916 and had had practically no experience in the medical practice of his profession since that date, having been employed by the Ministry of Pensions, since he joined the Ministry, on purely administrative duties of a subordinate nature during the past five years; and whether he had been told that he was to succeed an officer with overseas service and a war disability whose services were to be dispensed with, part of whose duties consisted in visiting pensioners at their homes and the holding of medical clinics.—Major G. C. TRAYNOR replied: The considerations governing the selection of medical officers of the Ministry of Pensions for further employment were fully explained in a reply which I gave the hon. and gallant Member on Feb. 12th, and it is due solely to those considerations that the officers mentioned in the question are being retained.

Boy Prisoner's Mental Condition.

Mr. SCURR asked the Home Secretary whether his attention had been called to the sentence imposed on Robert Oulagi, a boy of 18, at the Old Bailey on Feb. 26th; and if he would cause an inquiry to be held into the mental and physical condition of the prisoner before the punishment of 20 strokes with the cat was carried out.—Mr. LOCKER-LAMPSON (Under Secretary for the Home Department) replied: I have received reports showing that there is no medical reason why the sentence of the court on this prisoner should not be carried out. It will not, of course, be carried out until the expiration of the ten days within which the prisoner may apply to the Court of Criminal Appeal.

Mr. SCURR asked if there was not considerable evidence that the prisoner was absolutely abnormal.—Mr. LOCKER-LAMPSON said that the senior medical officer of Brixton Prison had reported very fully on this case and he stated that the prisoner was sane and in robust physical health and condition. His general bodily and mental development was far in advance of his actual age and there was no evidence of epilepsy. The doctor could not come to any other conclusion than that he was responsible for his actions.

High Death-rate at Singapore.

Mr. CECIL WILSON asked the Secretary of State for the Colonies whether he was aware that, in the course of an inquiry in 1905 into the high death-rate in Singapore, it was pointed out that one-fifth of the population was permanently on the sick-list and that much of the death and sickness was preventable; and what had been done since that time to improve housing and sanitary conditions and what amount of money had been spent on such improvements.—Mr. ORMSBY-GORE (Under Secretary for the Colonies) replied: I am calling on the Governor to supply a comprehensive report on the points raised in this question and will communicate further with the hon. Member as soon as it is received.

Lee Commission and Indian Medical Services.

Lieut.-Colonel FREMANTLE asked the Under Secretary of State for India when the Government would state their proposals for dealing with the recommendations of the Lee Commission with regard to the medical services in India; and whether the House would be given an opportunity of discussing them before any decision was arrived at.—Earl WINTERTON replied: My noble friend has not yet received the Government of India's recommendations, though he expects them very shortly. He would prefer to await them before giving any undertaking in reply to the last part of the question.

TUESDAY, MARCH 3RD.

Maintenance of Lunatics.

Mr. GROVES asked the Minister of Health whether, in view of the increase in the cost of maintenance of inmates of lunatic asylums now chargeable to boards of guardians and the inadequacy of the sum of 4s. per head repaid to the various unions under the Local Government Act, 1888, he would consider the introduction of legislation amending the Act in order to provide a repayment to boards of guardians of 50 per cent. of the cost incurred for the maintenance of such patients.—Sir KINGSLEY WOOD replied: My right hon. friend cannot undertake to introduce legislation on this subject at the present time. The grant in question was intended to make up the difference between the cost of maintenance in asylums and in Poor-law institutions, and the latest figures show that the average cost in asylums is only £10 a year more than the average cost in Poor-law institutions.

Medical Diary.

SOCIETIES.

THE ROYAL SOCIETY, Burlington House, Piccadilly, W.
 THURSDAY, March 12th.—4.30 P.M.—*Papers to be read*: Sir Charles Sherrington: Remarks on Some Aspects of Reflex Inhibition. E. G. T. Hartridge and F. J. W. Roughton: The Kinetics of Hemoglobin. III. (Communicated by Prof. J. N. Langley.)—*Paper to be read in title only*: S. B. Schryver, H. W. Buston, and D. H. Mukherjee: The Isolation of a Product of Hydrolysis of the Proteins Hitherto Undescribed. (Communicated by Prof. V. H. Blackman.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W. MEETINGS OF SECTIONS.

Monday, March 9th.

WAR: at 5 P.M.
 Award of the North Persian Forces Memorial Medal for 1923 to Wing-Commander Harold E. Whittingham, R.A.F.M.S.
 The Medal will be presented by Sir StClair Thomson, President of the Society.
Paper:
 Wing-Commander H. E. Whittingham, R.A.F.M.S.: The Treatment of Malaria by Novarsenobillon.

Tuesday, March 10th.

THERAPEUTICS AND PHARMACOLOGY: at 4.30 P.M.
Communications:
 Dr. J. Trevan, Mr. W. H. Gray, and Miss E. Boock: The Physiological Properties of Some Derivatives of Cocaine.
 Dr. W. J. Smith Jerome: The Unknown Factors of Gout.
 Miss Steabben: Observations on the Action of Colloidal Substances on Blood Elements and Antibody Content.
 PSYCHIATRY: at 8.30 P.M.

Paper:
 Dr. T. W. Mitchell: The Psycho-analytic Theory of Suggestion and Hypnosis.

Thursday, March 12th.

COMPARATIVE MEDICINE (Special Discussion: at 5.30 P.M.)
 TROPICAL DISEASES Infective Abortion in Cattle
 OBSTETRICS AND its Relation to Mediter-
 GYNÆCOLOGY ranæan Fever.

Opener:
 Prof. John Eyre.

Other Speakers:

Mr. L. E. W. Bevan, Sir Percy Bassett-Smith, Colonel J. C. Kennedy, Prof. Louise McIlroy, Mr. J. T. Duncan, Mr. Leslie Pugh, and others.

NEUROLOGY:

Clinical Meeting at the National Hospital for the Paralysed and Epileptic, Queen-square, W.C., at 8 P.M.
 Notes of Cases (concise and in a form suitable for publication) must reach one of the Hon. Secretaries of the Section not later than first post on Monday morning, March 9th.

Friday, March 13th.

CLINICAL: at 5.30 P.M. (Cases at 5 P.M.)
Cases:
 Sir Percy Bassett-Smith: Case of Raynaud's Disease.
 Dr. Bernard Myers: (1) Case of Chorea. (2) Case of Chorea in a Girl of Twelve.
 Dr. Parsons-Smith: Two Cases of Cardiac Disease.
 Mr. James Driberg: Case of (?) Tubercular Disease of Rib.
 Dr. L. S. T. Burrell: Case of Bronchiectasis.
 Other cases will be shown.

OPHTHALMOLOGY.

Clinical Meeting at Guy's Hospital, S.E. 1, at 5 P.M.

Cases:
 Mr. Ormond: (1) Case of Arachno-dactylia. (2) Case of Glioma of Retina Treated by Deep X Ray Therapy. (3) Case with "Hole in the Macula."
 Mr. O. G. Morgan: (1) Congenital Lagophthalmos. (2) Recurrent Third Nerve Paralysis in a Child.

Other cases will be shown.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, March 9th.—8.30 P.M., Discussion on the Fundus Oculi in General Medicine, to be introduced by Mr. Ernest Clarke, followed by Mr. R. Foster Moore, Dr. James Collier, and others.

BIOCHEMICAL SOCIETY.

MONDAY, March 9th.—5 P.M. (at the Lister Institute, S.W.)
Communications: F. W. Fox: The Cholesterol Content of Bile and its Bearing upon the Metabolism of Cholesterol and the Bile Acids. J. R. Marrack: The Total Base Content of Plasma. D. Hoffer and I. S. Maclean: The Action of Yeast on Lactic Acid. E. H. Lepper and C. J. Martin: (a) The Influence of Salt Concentrations on the CH of Buffer Solutions as Indicated by the Electrometric and Colorimetric Methods Respectively: (b) Can the CH of mixtures of NaHCO₃ and CO₂ in High Dilutions be Determined by the Hydrogen Electrode?

WEST KENT MEDICO-CHIRURGICAL SOCIETY, Miller General Hospital, Greenwich, S.E.
 FRIDAY, March 13th.—8.45 P.M., Mr. Hugh Davies: Some Interesting Abdominal Cases.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, March 9th, to SATURDAY, March 14th.—BARNES HALL, Royal Society of Medicine. A Discussion on Post-Graduate Teaching in London will take place on Wednesday, March 18th, at 6 P.M., Sir Arbuthnot Lane, Bt. (President of the Fellowship), will preside. All members of medical profession invited to attend, from whom criticisms of the existing arrangements and suggestions for improvement are desired.—WEST LECTURE HALL, Royal Society of Medicine. Lecture arranged by the Fellowship of Medicine and open to all members of the medical profession. Wednesday, March 11th, at 5.30 P.M., Mr. Oswald Addison on Cleft Palate.—CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd-street, W.C. Lecture-demonstrations in Diseases of the Eye. Daily in the afternoons.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Special Course in Medicine, Surgery, and Gynæcology. Lecture-demonstrations will be given in the Wards and Out-patient Departments.—NORTH-EASTERN FEVER HOSPITAL, St. Ann's-road, N., Wednesday and Saturday at 11 A.M., Demonstrations on the Diagnosis and Treatment of the Acute Infectious Diseases will be given by Dr. Frederic Thomson.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, March 9th.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Addison: Surgical Wards. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.

TUESDAY.—11 A.M., Dr. McDougal: Electrical Dept. 12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Mr. Tyrrell Gray: Surgical Wards.

WEDNESDAY.—11 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Burnford: Medical Wards. 4.30 P.M., Dr. Trevor Davies: Gynæcological Demonstration.

THURSDAY.—11 A.M., Sir Henry Simson: Gynæcological Wards. 2 P.M., Mr. Bishop Harman: Eye Dept. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

FRIDAY.—10.30 A.M., Dr. Dowling: Skin Dept. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Vlasto: Throat, Nose and Ear Dept.

SATURDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: FEB.-MARCH, 1925.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, March 9th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Syphilis of the Nervous System (1): Dr. Adie.

TUESDAY, March 10th.—2 P.M., Out-patient Clinic: Dr. Adie. 3.30 P.M., The Myopathies: Dr. Birley.

THURSDAY, March 12th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Recovery of Function after Nerve Anastomosis: Dr. Bailey.

FRIDAY, March 13th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Surgery of the Sympathetic System: Mr. Percy Sargent.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE PATHOLOGY OF THE NERVOUS SYSTEM.

THURSDAY, March 12th.—12 noon, The Neuron: Dr. J. G. Greenfield.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM.

MONDAY, March 9th.—12 noon, Cranial Nerves: Dr. Hinds Howell.

The Fee for this Course will be £2 2s.

Dr. H. J. MacBride will give a COURSE OF EIGHT CLINICAL DEMONSTRATIONS, chiefly on METHODS OF EXAMINATION OF THE NERVOUS SYSTEM, in the Wards at 10 A.M. on Tuesdays and Fridays, if sufficient entries are received. The Fee for this Course will be £2 2s.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE NEUROLOGY OF THE EYES.

WEDNESDAY, March 11th.—3.30 P.M., The Oculomotor Nerves: Mr. Leslie Paton.

Applications for this Course should be made early. Fee £5 5s. if taken as a separate Course, or £3 3s. if taken with the General Course.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course. Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course. J. G. GREENFIELD, Dean of Medical School.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

TUESDAY, March 10th.—4.30 P.M., Mr. E. S. Pierrepont: The Mouth as an Aid to Diagnosis.

FRIDAY.—4.30 P.M., Mr. E. Gillespie: Enlargements of the Prostate.

Daily: In-patient and Out-patient Clinics in General and Special Departments, Operations, &c.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, W.
 SATURDAY, March 7th and 14th.—3 P.M., Sir Ernest Rutherford: The Counting of the Atoms.
 TUESDAY, March 10th.—5.15 P.M., Prof. E. N. da C. Andrade: Evolution of the Scientific Instrument.
 THURSDAY.—5.15 P.M., Dr. Leonard Hill: Biological Action of Light.
 HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
 THURSDAY, March 12th.—4 P.M., Mr. Pitts: Affections of the Gums in Children.
 QUEEN CHARLOTTE'S MATERNITY HOSPITAL POST-GRADUATE LECTURES, Marylebone-road, N.W.
 THURSDAY, March 12th.—5 P.M., Mr. C. S. Lane Roberts: Venereal Diseases in Pregnancy.
 CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.
 FRIDAY, March 13th.—4 P.M., Mr. Walwyn Thomas: Acute Mastoiditis.
 ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C.
 TUESDAY, March 10th.—5 P.M., Dr. H. G. Adamson: Rodent Ulcer.
 THURSDAY.—5 P.M., Dr. H. MacCormac: Malignant Growths.
 MANCHESTER ROYAL INFIRMARY.
 TUESDAY, March 10th.—4.15 P.M., Mr. H. H. Rayner: Cancer of the Breast—A Review of the Results of Treatment.
 FRIDAY.—4.15 P.M., Dr. E. M. Brockbank and Mr. E. D. Telford: Clinical Cases.
 ANCOATS HOSPITAL.
 THURSDAY, March 12th.—4.30 P.M., Dr. Norman Kletz: Dyspepsia.
 CHADWICK PUBLIC LECTURES.
 MONDAY, March 9th.—8 P.M. (at the Inner Temple Hall, London), The Lord Newton: The Necessity for Legislation with Regard to Smoke Abatement.
 ST. ANDREWS INSTITUTE FOR CLINICAL RESEARCH.
 TUESDAY, March 10th.—4 P.M., Dr. Anderson and Dr. MacLennan: Albuminuria and the Specific Fevers. Discussion.
 THE PEOPLE'S LEAGUE OF HEALTH.
 Lectures on What We Should Eat and Why, at the Medical Society of London, 11, Chandos-street, W.
 WEDNESDAY, March 11th.—6 P.M., Dr. H. Scurfield: Principles of Infant Feeding.

Appointments.

GRIFFIN, A. J. B., M.B., Ch.B. Liverp., D.P.H., has been appointed Assistant Medical Officer of Health, Walsall.
 HOLDEN, O. M., M.D., Ch.B., Birm., D.P.H., Medical Officer of Health, Blackburn.
 Certifying Surgeons under the Factory and Workshop Acts:
 WADE, A. R., L.M.S.S.A. (Highbridge, Somerset);
 WILLIAMS, R. T., M.B., B.S. Lond. (Llanfairfechan, Carnarvon); McILRAITH, L.R.C.P., L.R.C.S. Edin., L.R.F.P.S. Glasg. (Frickheim, Forfar); McCLISTER, D., M.B., B.Ch. Belf. (Stillington, Durham); and LUNN, J. (Bruton, Somerset).

Vacancies.

For further information refer to the advertisement columns.
 Albert Dock Hospital, Connaught-road, E.—H.S.'s at rate of £110.
 Ashton-under-Lyne, District Infirmary.—H.S. at rate of £150.
 Ayr County Hospital.—H.S. and Jun. H.S. at rate of £100 and £80 respectively.
 Barnet, Wellhouse Hospital.—Asst. Res. M.O. £150.
 Birmingham and Midland Hosp. for Dis. of Nervous System, Park-row.—Clin. Asst. for Out-patient Dept. at rate of £50.
 Birmingham Asylums Committee.—Consulting S.
 Birmingham, Queen's Hospital.—Third Phys. £50.
 Bradford Royal Infirmary.—H.S. £150.
 Bristol Royal Infirmary.—Hon. Med. Reg.
 Bristol, Southmead Hospital.—Res. Med. Supt. £650.
 Burton-on-Trent Infirmary.—H.S. £150.
 Cardiff, Welsh National School of Medicine.—Asst. Lecturer in Dept. of Physiology. £400.
 City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Anaesthetist.
 Derbyshire County Council.—M.O.H., &c. £1400.
 Doncaster Royal Infirmary.—Hon. Ophth. S.
 Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at rate of £110.
 Federated Malay States.—Research Studentship in Tropical Medicine. £700.
 Freemasons Hospital and Nursing Home, 237, Fulham-road, S.W.—R.M.O. at rate of £250.
 Guy's Hospital Dental School.—Dental Travelling Scholarship.
 Halifax Royal Infirmary.—Third H.S. at rate of £150.
 Hospital for Diseases of the Throat, Golden-square, W.—Hon. Surg. Reg.
 Hospital for Epilepsy and Paralysis, Maida Vale, W.—R.M.O. and H.P. at rate of £150 and £100 respectively.
 Hull, Victoria Hospital for Sick Children, Park-street.—Res. H.P. £80.
 Inverness, Northern Infirmary.—Jun. M.O. £100.
 Kingston-on-Thames, Kingston and District Hospital.—Second Asst. Res. M.O. at rate of £300.

Liverpool Open-air Hospital for Children, Leasowe, for Non-Pulmonary Tuberculosis.—Jun. M.O. £200.
 London Homœopathic Hospital, Great Ormond-street, W.C.—Third Anaesthetist. £50.
 London Hospital, E.—First Asst. to Surgical Firm. £400.
 Manchester, Christie Hospital.—Cancer Research Worker. £500.
 Manchester, St. Mary's Hospitals.—Two H.S.'s. Each at rate of £50.
 Manchester University.—Lecturer in Morbid Anatomy and Histology. £500.
 Metropolitan Asylums Board, Infectious Hospitals Service.—Asst. M.O.'s. £500.
 Metropolitan Hospital, Kingsland-road, E.—S. for Dis. of Nose, Throat, and Ear. Also Hon. Anaesthetist.
 Middlesex Hospital and Medical School, W.—Obstet. and Gynecological Reg. £300. Also University Chair of Biochemistry. £800.
 National Hospital for Dis. of the Heart, Westmoreland-street, W.—Res. M.O. at rate of £150. Also Out-patient M.O. at rate of £125.
 National Hospital for the Paralysed and Epileptic, Queen-square, W.C.—Asst. Ophth. S.
 Portsmouth, Royal Hospital.—Sen. H.S. at rate of £200.
 Preston and County of Lancaster Royal Infirmary.—Third H.S. £150.
 Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—R.M.O. £200. Also Two H.P.'s and Cas. H.S. Each at rate of £100.
 Richmond, Surrey, Royal Hospital.—Asst. H.S. £100.
 Royal Chest Hospital, City-road, E.C.—Phys.
 St. Peter's Hospital for Stone, &c., Henrietta-street, Covent Garden, W.C.—H.S. at rate of £75.
 Sheffield Royal Hospital.—Hon. Radiologist.
 South London Hospital for Women, South Side, Clapham Common, S.W.—H.P. and Three H.S.'s in each case at rate of £50.
 Suva, Fiji.—Port M.O. and Bacteriologist, &c. £750.
 Walsall General Hospital.—Hon. Pathologist. 50 guineas.
 West Ham Union, Central Home, Union-road, Leytonstone, E.—Res. Asst. M.O. £441.
 West London Hospital, Hammersmith-road, W.—H.P. and Two H.S.'s. Each at rate of £100.
 West Riding County Council.—Dist. Tuberculosis O. £600.

Births, Marriages, and Deaths.

BIRTHS.

BALL.—On Feb. 21st, at Warwick-mansions, Pond-street, Hampstead, the wife of Norman Dyer Ball, M.B., of a son.
 CONNAN.—At "Sanno," Cotsford-avenue, New Malden, on Feb. 23rd, to Annie Dorothy (née Mackintosh), wife of Dr. D. M. Connan—a daughter.
 HARE.—On Feb. 22nd, at Earl Soham, Suffolk, the wife of W. Theodore Hare, M.C., M.R.C.S., L.R.C.P., of a son.

MARRIAGES.

GARFIELD—ELMAN.—On Feb. 25th, Montagu Garfield, M.R.C.S., L.R.C.P., L.D.S. Eng., of Palmeira-mansions, Hove, to Marguerite Elman, M.R.C.S., L.R.C.P., of Amhurst-road, London, E.
 HILL—GLAISYER.—On Feb. 18th, at Christ Church, Hampstead, Arthur Hilary Clifton Hill, M.R.C.S. Eng., L.R.C.P. Lond., to Ellen Phoebe, youngest daughter of Mr. and Mrs. Edmund Glaisyer, of Putney.

DEATHS.

DE WATTEVILLE.—On Feb. 24th, near Geneva, Armand de Watteville, M.D., late of Welbeck-street, W., in his 79th year.
 GRAHAM BROWN.—On Feb. 28th, at Edinburgh, John James Graham Brown, M.D., F.R.C.P. Edin., aged 71.
 HARDING.—On Feb. 25th, at Sydney-place, Bath, suddenly, Alfred William Harding, B.A., M.B., M.R.C.S. Eng., aged 78.
 VINRACE.—On Feb. 27th, at "Deenhurst," Moseley, Birmingham, Emelin S. Vinrace, only daughter of the late John Vinrace, M.D.
 WILLIAMS.—On Feb. 20th, at Pen-Bre, Bangor, Richard Williams, J.P., M.R.C.S., Ophthalmic Surgeon, late of Rodney-street, Liverpool.
 N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE LATE MR. J. F. STEEDMAN.—John Francis Steedman, F.R.C.S. Eng., who died recently from heart failure while attending an International Rugby football match, was an old Bart.'s man who qualified M.R.C.S. Eng. in 1883, taking the F.R.C.S. two years later. He was born 70 years ago in Shropshire. Mr. Steedman had been in private practice in Streatham for nearly 30 years and was greatly esteemed by all who knew him in that district. He was keenly interested in local hospital and charitable work and for 20 years was hon. medical officer at the Magdalen Hospital, Dewstead-road. He assisted in the work of the Streatham Red Cross Hospital during the war. Mr. Steedman was an enthusiastic sportsman, playing cricket, golf, and lawn tennis, and to the end took a great interest in all games. He leaves a widow and five children.

Notes, Comments, and Abstracts.

THE OPERATIVE TREATMENT OF UTERINE DISPLACEMENTS.

BY ARTHUR E. GILES, M.D., B.Sc.LOND., F.R.C.S.ED.,
GYNÆCOLOGIST, PRINCE OF WALES'S HOSPITAL, TOTTENHAM;
CONSULTING SURGEON, CHELSEA HOSPITAL FOR WOMEN.

UTERINE displacements fall naturally into two groups:
(1) Backward displacements: Retroversion and retroflexion;
(2) downward displacements: Prolapse and procidentia.

Backward Displacements of the Uterus.

Retroflexion is in some cases a matter of shape more than of position; it is indeed possible for the fundus to be sharply bent back over the cervix, while the uterine axis as a whole maintains almost its normal position. Such a retroflexion may be regarded as developmental, and is strictly analogous to acute antelexion, which is a matter of conformation rather than one of position. In other cases, when the uterine tissues are lax and the axis of the uterus has become tilted backwards, retroflexion may occur as a secondary condition, when it may be regarded as an exaggerated form of retroversion. In speaking of retroversion in the following remarks the term will be used so as to include cases complicated by retroflexion.

Formerly the treatment of retroversion by pessaries was the rule; operative treatment was the exception. Now this is reversed. The increasing safety of abdominal operations has been the primary factor in the change; education of feminine public opinion has followed. No healthy and nice-minded woman likes either the idea of having a foreign body in her vagina or the necessity for frequently recurring examinations. It becomes as obvious to patients as it is well known to their doctors that pessaries have the effect of setting up or increasing unpleasant discharges; and it has become known to them, as it has long been to us, that the long-continued irritation of a pessary in the vagina is a possible cause of malignant disease. Many women have endured the wearing of pessaries, even for years, simply because they did not know that there was any other mode of treatment, and because, even with the attendant disadvantages of pessaries, they were at least more comfortable with one than without one. Once the more excellent way is shown to them, the great majority of women choose operation in preference to pessaries.

There is only one class of case of retroversion in which pessaries are even permissible, and that is when the uterus is freely mobile and there are no complications. When the uterus is adherent, the introduction of a pessary is not only futile, but harmful. Of course, it ought not to be possible for a pessary to be introduced in such a case, because the first and cardinal rule in the treatment of retroversion by a pessary is that the displacement must be corrected before a pessary is put in. Obviously, if this rule be followed, the fixation of the uterus cannot be overlooked, because in such a case the displacement cannot be corrected. It must be admitted that gynecologists do have women coming to them wearing a pessary with an adherent retroversion, and wondering why they still feel discomfort; and the admission must be made sorrowfully, because the point is explicitly stated in text-books, and has repeatedly been emphasised in lectures both to students and to post-graduates. The fact that I have come across such cases recently makes me feel that it is still necessary that it should be stated afresh.

The other condition in which pessary treatment is definitely barred is when there is disease of the uterine appendages, or of the uterus itself. Here the accompanying disease is more important than the displacement, and should be treated, surgically if necessary, and the displacement can be dealt with at the same time.

Operative Treatment of Retroversion.—There are several ways of dealing surgically with a retroversion. It is not necessary to make more than a passing reference to the fantastic view that has been seriously propounded by some recognised teachers of gynecology that retroversion can be cured by curetting. An examination of this view must at once convince the impartial observer of its absurdity. Nor need we consider seriously the operation of vaginofixation; it has no possible advantages over other procedures, and it has the manifest disadvantage that it leaves the uterus immobilised in a faulty position. Two types of operation are worthy of consideration: *Shortening of the round ligaments*, and suture of the uterus to the abdominal wall—an operation that is properly described as *hysteropexy*.

Shortening of the Round Ligaments.—Historical reviews refer to the extraperitoneal method of shortening the round ligaments devised independently by Alexander and

by Adams, and known usually by their joint names as the *Alexander-Adams operation*. It served its purpose at the time, as a pioneer method; its drawbacks were so evident that it fell out of use and was replaced by better procedures. The present-day methods are intraperitoneal, and are founded on the operation devised by Gillian. His plan was to reflect the skin back for a short distance on each side of the median incision, pass a forceps through muscles, fascia, and peritoneum on either side, pick up the round ligament, draw it out through the hole made in the muscle and fascia, and suture a loop of it there. Others pass a purse-string suture along the course of the round ligament from where it enters the internal inguinal ring to its origin in the uterine fundus. When the two ends of the suture are drawn together and tied the round ligament is crumpled up in a close loop. A more particular modification of Gillian's operation is to strip back the skin as he does, but low down over the external inguinal rings. A curved forceps is then passed up the inguinal canal and brought out at the internal inguinal ring; the round ligament is seized and brought out through the inguinal canal. This method is theoretically very sound; but there is a definite risk of wounding the deep epigastric artery, and as a result of this accident troublesome hæmorrhage occurs.

Suture of the Uterus.—The idea of suturing the uterus to the abdominal wall is 30 years old. Yet there are few operations concerning which more confusion prevails at the present time than we find centred round the suturing of the uterus. The confusion lies in the terms *ventrofixation* and *ventrosuspension*.

Ventrofixation, as originally devised, was as follows: The uterine fundus was brought up and doubled forward; silk or silkworm-gut sutures were passed through the muscle, fascia, and peritoneum of one side, then through the posterior wall of the uterus, then out through the peritoneum, fascia, and muscle of the other side. When the sutures were tied the uterus lay with its posterior surface in contact with the abdominal wall. The advantage of the operation was that the results were permanent; the disadvantage was that if carried out in a woman of child-bearing age and she became pregnant, serious trouble was bound to occur.

Ventrosuspension.—In this operation the sutures were passed through the peritoneum only on either side, and through the anterior surface of the uterus. The advantage was that a subsequent pregnancy was not interfered with; the disadvantage was that the peritoneal attachment stretched so readily that a long thin band soon formed, allowing the uterus to fall back as badly as ever.

Neither of these operations is ever done to-day; neither has been done for many years past unless by operators who do not know the correct way to suture the uterus. The term *ventrosuspension* is very seldom heard. But *ventrofixation* is still spoken of to describe the very different operation that is done now. The consequence is that many people with imperfect knowledge of this subject—and it would appear that we must include in this category a number of quite eminent gynecologists—use the term *ventrofixation*, which they know, in speaking of the modern operation, which they do not know, and proceed to condemn it wholeheartedly, saying that it is a most dangerous operation to perform in a woman of child-bearing age. The truth is that this observation would be entirely correct if it referred to the original operation, which is not performed, but it is entirely incorrect when applied to the modern operation. This operation I shall now describe.

Hysteropexy.—In view of the confusion entailed by the use of the words *ventrofixation* and *ventrosuspension*, I long ago decided to abandon both words, and to use the non-committal word *hysteropexy* to describe the modern operation. The principle of it is that the sutures are passed through the muscles and fascia, as in *ventrofixation*, whereby the stability of the attachment is secured. But in the uterus they are passed on the anterior surface, as low as possible above the bladder reflection, and all of them lower than the uterine fundus. The result of this is that in case of pregnancy the uterus is free to expand, and pregnancy and labour proceed normally. In saying this I am not speaking of what, theoretically, *should happen*, but of what, in practice, *has happened*. Among over 1200 hysteropexies which I have myself carried out, a considerable number were done in women of child-bearing age, either married at the time or who married subsequently. Inquiries into their later history have resulted in information concerning over a hundred cases in which pregnancy has occurred and labour has taken place as normally as in women who have not been operated upon. In the majority of cases information derived from the patients has been corroborated and supplemented by letters or verbal communications from the medical practitioners who have attended them in their confinements. Therefore, I can assert confidently that hysteropexy, properly carried out, is a safe and proper operation to perform on women of child-bearing age.

Hysteropexy versus Shortening of the Round Ligaments.—While I have performed hysteropexy many times, I have shortened the round ligaments in relatively few cases. It is a proper question that I should be asked why I prefer hysteropexy. The answer is that these are operations whose merits stand or fall by their results, and that in judging of results one cannot do otherwise than be guided by one's own experience. The two outstanding questions are: (1) What is the effect of the operation on pregnancy, and of pregnancy on the operation? (2) Are the results permanent as regards the correction of the displacement? With regard to hysteropexy, I have answered the first part of the first question, and the answer to the second part is that I have examined a large number of patients after the confinement and have found the uterus still attached to the abdominal wall. With regard to shortening of the round ligaments, I have no experience of cases of subsequent pregnancy; but certainly better results could not be obtained than have followed hysteropexy. With regard to the second question, it has been my experience to come across a number of cases operated upon by other surgeons, where the round ligaments had been shortened, and examination showed that the uterus had fallen back into a position of retroversion. A careful statistical investigation of cases examined after hysteropexy, often after many years, showed that the attachment remained good in about 98 per cent. I should much like to see carried out an investigation of the after-results of a large number of cases of shortening of the round ligaments; and if the results should prove to be better than those of hysteropexy, I would gladly follow the better method. At present I can come to no other conclusion than this—that hysteropexy, which is a simple and safe operation, is as safe as it is possible to be from the point of view of subsequent childbirth, and that it gives more permanently good results than does the operation for the shortening of the round ligaments.

Downward Displacements of the Uterus.

These include the various degrees of prolapse and procidentia of the uterus together with the frequently associated prolapse of the vaginal walls. No form of prolapse can be cured by pessary treatment. A considerable degree of comfort can be obtained by means of pessaries, but a woman who chooses a pessary in preference to operation will have to wear one for the rest of her life. The drawbacks of pessaries detailed in the remarks on retroversion remain the same when they are used for prolapse—the frequent examinations, the discharge, and the chronic irritation which in some cases may pave the way for malignant disease.

The secret of success in the operative treatment of prolapse is to leave no part of the prolapse untreated. For example, when a marked cystocele complicates the descent of the uterus, it is not sufficient to fix up the uterus; the cystocele would remain, and would be capable of causing as much discomfort as the prolapse of the uterus itself. In the same way, when the uterus is heavy and markedly prolapsed, it is not sufficient to repair the perineum and do an anterior colporrhaphy, for the heavy uterus will continue to press down and cause the typical "bearing-down" feeling. For a slight prolapse of a small uterus associated with a deficient perineum and a cystocele a perineorrhaphy and anterior colporrhaphy may suffice. If the uterus be heavy and hyperplastic, or much prolapsed, or both, I regard the suturing up of the uterus as essential. There is a doctrine, emanating chiefly from Manchester, to the effect that an abdominal operation should never be done for prolapse, and that the proper treatment is amputation of the cervix, an extensive anterior colporrhaphy and a thoroughgoing perineorrhaphy. My belief is that this doctrine is fundamentally unsound, and in practice most pernicious. The hyperplasia in these cases, for which the amputation of the cervix is ostensibly performed, is in part apparent more than real. When the uterus comes down, bringing down the vaginal walls with it, the cervix appears to be elongated, because the vaginal fornix is drawn down in a cone-like fashion simulating a long cervix. When the uterus is pushed up into place the true state of things is at once evident. Such a cervix certainly does not need to be amputated. Moreover, such hyperplasia as is present—and there is often some hyperplasia of the supra-vaginal portion of the cervix—is due to the prolapse itself, and when the uterus has been slung up to the abdominal wall the hyperplasia clears up.

But my objection to amputation of the cervix in these cases is not based only on the fact that it is unnecessary; a still more important objection is on the ground that it is harmful. It leaves a scarred and mutilated stump in the vagina, and with the accompanying thorough colporrhaphy there is a great deal of cicatricial tissue in and round the vaginal vault. I saw a case that had been treated in this way, and indeed it was a sorry sight. Scar-tissue alternated with raw patches. The patient was a still young woman

anxious to have another baby, and the outlook seemed pretty hopeless. This mutilating treatment is done in order to avoid opening the abdomen and slinging up the uterus; I am certain that the woman is left in a far more normal condition with her cervix intact and the uterus attached to the abdominal wall, and in the latter case the chances of pregnancy and natural labour are not in the least degree impaired.

In many cases an old tear of the cervix is present, with that eversion of the mucous membrane commonly called "erosion," but more correctly described as "ectropion." It is good procedure to repair such a cervix by means of a trachelorrhaphy, and when the uterus is hyperplastic, or there is a history of menorrhagia or discharge, a curetting should precede the trachelorrhaphy. This is a very different matter from an amputation of the cervix. Repair leaves a cervix that is practically normal, and serviceable for child-bearing. When anterior colporrhaphy is required, the procedure will vary according to the degree of the vaginal prolapse. With a simple elongation of the anterior vaginal wall, it is sufficient to remove a diamond-shaped area and suture the cut edges so as to form a transverse seam. When the bladder protrudes markedly, a good method is to make a vertical incision and dissect two lateral flaps. The bladder is thus exposed, and with the help of a few light touches with the scalpel it can be separated from the front of the cervix and pushed up with a swab. When it is sufficiently out of the way, the bases of the flaps are brought together with two or three mattress sutures; the redundant portion of the flaps is cut off, and their edges brought together with a continuous catgut suture.

When all that is necessary in the way of vaginal and cervical repair has been done, the abdomen is opened and the uterus is sutured to the abdominal wall, as previously described. The advantage of hysteropexy over shortening of the round ligaments, which I regard as definite in cases of retroversion, is even more pronounced in dealing with prolapse and procidentia. The round-ligament operation will hardly ever hold up permanently a heavy prolapsed uterus. Sometimes the case may be complicated by the presence of a small ovarian cyst or some fibroids, and ovariectomy or a myomectomy can then be carried out before the uterus is sutured. Sometimes a patient with procidentia is sent to us with the suggestion that a hysterectomy should be done. To accept the suggestion would be a very great mistake. If such a uterus be removed, the sequel is almost always a very troublesome recurrence of prolapse of the vaginal walls, which is apt to be most difficult to deal with. It is much better to retain and fix up the uterus, and so use it to pull up and support the vaginal walls. So important do I consider this point that if I have to deal with a prolapsed uterus with fibroids, the fact of the prolapse would induce me to do a myomectomy even in cases where a hysterectomy would otherwise be certainly indicated.

It will be seen that in many cases several procedures are required when dealing with downward displacements of the uterus. We may summarise them as follows:—Hysteropexy and perineorrhaphy, when the prolapse is associated with a deficient perineum. Hysteropexy and anterior colporrhaphy, when the perineum is good, but a cystocele is present. Hysteropexy, anterior colporrhaphy and colporrhaphy, when cystocele and rectocele and a deficient perineum complicate the prolapse. Hysteropexy, curetting, and trachelorrhaphy, when the vaginal walls are good, but the cervix is torn. Hysteropexy, curetting, trachelorrhaphy, anterior colporrhaphy, and perineorrhaphy, when the vaginal walls and cervix also want attending to. This whole operation can be completed in about an hour when no time is wasted. Any or all of these procedures may be carried out without hesitation in a woman of child-bearing age with the assurance that pregnancy and labour will not be prejudiced thereby.

AN INDISPENSABLE YEAR BOOK.

"Burdett's Hospitals and Charities, 1925" (London: The Scientific Press, Ltd. Pp. 1019. 17s. 6d.), has reached us. This year book, founded 35 years ago by the late Sir Henry Burdett, is too well known to need detailed description. It is sufficient to say that it gives an account of over 8000 institutions and serves as an exhaustive record of current charitable work. As a guide to British and colonial hospitals and asylums, medical schools and colleges, nursing and convalescent institutions, sanatoria, dispensaries, and benevolent institutions it is indispensable; the index is well compiled and comprehensive. Among new features may be noted a section in which seamen's hospitals throughout the world are grouped together, and a new sub-section, which contains a list of the London, provincial, and Scottish settlements for social work. The directory of institutions overseas has been enlarged, Africa taking a good share of the newly allotted space.

A Study

OF

TWINS IN HEALTH AND DISEASE.

A Presidential Address delivered before the Manchester Medical Society on Feb. 4th, 1925,

BY GEORGE R. MURRAY, M.D., F.R.C.P.,

PROFESSOR OF SYSTEMATIC MEDICINE IN THE VICTORIA UNIVERSITY; SENIOR PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

THE simultaneous start on the voyage of life of two identical individuals presents a unique opportunity of observing the development of hereditary characteristics and of comparing them with those resulting from the "changes and chances of this mortal life." As Francis Galton¹ aptly expresses it, "twins have a special claim upon our attention; it is that their history affords means of distinguishing between the effects of tendencies received at birth, and of those that were imposed by the special circumstances of their after-lives." Thus we find that the lives and characters of twins have always afforded a fascinating theme both in fact and fiction.

A study of the pathology of disease as it affects the different races of mankind has yielded much useful information as to modes of infection and variations in immunity. The occurrence of familial diseases, such as hæmophilia, is also highly instructive, but an examination of the incidence of disease in twins provides special opportunities for tracing the origin of certain maladies. The material for such an inquiry is probably much greater than might be expected, for Siemens² was able to obtain in Munich alone the addresses of 100 homologous twins of which he had been able to examine 50 pairs. In this country there must be a great deal of useful information as to the health and progress of twins which has been gathered at the various welfare centres and which only awaits investigation to yield valuable results.

CLASSES OF TWINS.

There are three distinct classes of twins, and so many synonymous terms have been used in describing them that confusion is apt to arise if their meaning is not clearly understood. First, there is the most important class of twins which arise from a single ovum and are described as "monozygotic," "homologous," "monochorionic," "uniovular," "one-egg," "similar," or "identical" twins. Second, there are those which arise from two separate ova fertilised at the same time, known as "dizygotic," "heterologous," "dichorionic," "binovular," "two-egg," "dissimilar," "fraternal," or "pigeon" twins. Third, there are the conjoined twins which show all degrees of conjunction from a slight union, as in the case of the Siamese twins, up to a high degree of fusion as in the various forms of double monsters, which are always developed from a single ovum.

Uniovular twins are always of the same sex, they are always enclosed in a single chorion, and are provided with a single placenta. They are usually almost identical in appearance, and are the most important in considering the incidence of disease in such similar individuals. Homologous twins are not common, and the definite proof of their origin from a single ovum can only be obtained by an examination of the placenta and foetal membranes at the time of their birth. As such evidence is rarely obtainable we must, for all practical purposes, conclude that when twins of the same sex are alike in appearance, with the same colour of hair and eyes, and the same type of skin they are monozygotic in origin. Binovular twins are not of so much interest, as they do not resemble each other more closely than other brothers and sisters born at different times, but they are subjected to similar influences during gestation and early childhood. They may be either of the same or of opposite sexes. Conjoined twins, when viable, are of interest as they are uniovular, but few of them survive.

5298

FREQUENCY AND PROPORTION OF MULTIPLE BIRTHS.

The frequency of multiple births varies in different localities. Kleinwachter³ quotes statistics collected by Wappaus of 19,698,322 pregnancies, which resulted in the birth of 19,930,556 children. In this large number there were 19,468,832 single children, 226,807 twins, 2623 triplets, 59 quadruplets, and 1 quintuplet, which gives 1 twin birth in about every 87 pregnancies. The proportion of twin births varies in different towns: thus Kurschner found there was 1 twin birth to 158 single births in Naples, 1 to 126 in Palermo, 1 to 88 in Berlin, 1 to 85 in London, 1 to 84 in Paris, 1 to 74 in Vienna, 1 to 52 in Heidelberg, and 1 to 57 in Dublin. Of 1,339,975 births in the United States in 1917, 1 in 93 was a twin birth (Abt).⁴ It has been estimated by Newman⁵ that one-half of the twins of the same sex are uniovular and that one-fourth of the total number of human twins belong to this class, whereas Ballantyne⁶ estimates that similar twins occur in only 12.25 per cent. of all twin births. It is therefore not surprising that, while we find extraordinary similarity in some twins, in the majority there are well-marked differences.

CAUSES OF TWINS.

It has generally been considered that "identical" twins are the result of fertilisation of a single ovum by two spermatozoa. Little, however, is really known of the causes of twinning in man. The experiments of Newman on the eggs and embryos of the starfish of the Pacific coast (*Patiria miniata*) led him to the conclusion that a retardation of the rate of development, such as occurs in unfertilised parthogenetic eggs, or in those which are too crowded, is a direct cause of twinning. He quotes Korchelt's experiment in which, after excision of a central portion of an earthworm, the anterior and posterior portions regenerate into double or even triple heads or tails, and regards this as a result of retardation following the operation. This question has also been studied in fish and especially in trout, and separate one-egg twins are believed to arise either from the appearance of two embryonic rudiments on one blastoderm or the presence in the egg of two separate blastoderms. In trout there also occur conjoined twins of the "autosite-parasite" variety which occurs in man as in the case of "Lulu." Identical twins may also arise in trout. In the armadillo of Texas (*Dasypus novemcinctus texanus*) two pairs of twins (quadruplets) normally are developed from a single ovum so that all members of the litter are of the same sex and all are alike, and Newman suggests that this is also due to retardation of the development resulting from slow action of the corpus luteum.

DIFFERENCES AND SIMILARITIES OF TWINS.

In uniovular twin pregnancy in women a larger number are males and the mothers are usually near either the beginning or the end of the child-bearing period. The difference in weight at birth is often considerable, and this is attributable to an inequality in the vascular supply to each twin during pregnancy. Abt⁴ mentions a case in which at birth one twin weighed 6 lb. and the other only 3 lb. Three years later the former was normal and the latter defective in development and weighed only 20 lb.

All the familiar anecdotes of the mistakes and practical jokes which have arisen from the similarity of twins relate to the uniovular variety. This type of twin has often afforded useful material for the dramatist and for the novelist. The Heavenly Twins, Castor and Pollux, the sons of Leda, according to classical tradition, were the result of the union of Zeus, in the form of a swan, with their mother. One tradition even states that Leda brought forth two eggs, from one of which Castor and Pollux were born and Helen from the other, so that they were one-egg twins. The earliest play in which twins appear is the "Menaechmi" of Plautus. In this play the similarity between Menaechmus of Epidamnus and Menaechmus Sosisles is thus described by Messenio, the servant of

L

the latter: "But I never beheld one person more like another person. Neither water, believe me, is ever more like to water nor milk to milk, than he is to you, and you likewise to him." Owing to this remarkable similarity the brothers, who are unaware of each other's presence in Epidamnus, unwittingly personate each other on various occasions and so give rise to many amusing situations until mutual recognition solves their difficulties at the end of the play. The "Comedy of Errors" is largely based on this play, but the situations are rendered rather more complicated by the introduction of the twin Dromios as attendants on the twin brothers Antipholus of Syracuse and Antipholus of Ephesus. In the words of the Duke of Ephesus:—

"These two Antipholuses, these two so like,
And these two Dromios, one in semblance."

Shakespeare well expresses the similarity of two pairs of homologous twins. It is notable that in this play these twins are rightly of the same sex, whereas in *Twelfth Night* Viola, dressed as a man, is identical in appearance and manner with her twin brother Sebastian, so that when they meet Orsino exclaims:—

"One face, one voice, one habit, and two persons;
A natural perspective that is and is not."

and Antonio asks:—

"How have you made division of yourself?
An apple, cleft in two, is not more twin
Than these two creatures."

In the *Corsican Brothers* Alexandre Dumas pictures two similar twins who were conjoined at birth but separated afterwards by an operation. The two brothers Louis and Lucien are described as being closely alike in appearance though differing in temperament and in tastes. Dumas draws on his imagination however in making both twins subject to the same physical and moral sensations, so that at the moment when Louis received a fatal bullet wound beneath the right sixth rib in fighting a duel at Vincennes, Lucien, who was in Corsica, felt a violent blow in the side, then found a bright-red mark in the same situation and knew his brother had been killed. It is said that in some cases both twins suffer from their origin or that one may prove himself a better man than the other all through life. Twinship appears to be a handicap, as it has been maintained that no "similar" twins have acquired great intellectual distinction. The two Scotts of Newcastle, who afterwards became Lord Stowell and Lord Eldon, were both "dissimilar" twins, as the former was born with a sister in 1745, and the latter with another sister in 1751. It may be mentioned that in this remarkable family, a third pair of twins, a son and daughter, were still-born about 1754. Jacob and Esau, the most ancient pair of twins on record, differed so much both physically and mentally that we may conclude that they were binovular in origin. The earliest record of English twins who became famous appears to be of the "Biddenden Maids," who are reputed to have been born in 1100 in the village of this name in Kent. They lived for 34 years and left money for the making of cakes, with an impression marked upon them for distribution to the poor on Easter Day. This impression shows them united at the elbows. Ballantyne,⁶ however, thinks this is improbable as it would be unique and suggests that they were probably pygopagous twins, united by the nates, and that the representation of the union by the arms was due to their going about with their arms round each other's necks. Many well-known English families have produced twins, and some more than one pair. Thus, in Brittain's well-known case a woman had 25 children, including twins 10 times. This tendency may appear in different branches of the same family. The striking similarity in the appearance of identical twins is shown in many well-known cases in all ranks of life, whose portraits not infrequently appear in the daily and weekly illustrated papers. In a recent case before the Law Courts of New Jersey it was stated that one twin, who closely resembled his

brother even in his birth-marks, had so successfully personated him for two years that his sister-in-law, being ignorant of her husband's death, did not detect the fraud. When the surviving twin was accused of bigamy both his wife and his brother's widow claimed him as husband, as he used to spend five days in the week with the former in New Jersey and two days with the latter and her sons in Philadelphia.

RESEMBLANCES IN CAREERS OF TWINS.

Not only do twins resemble each other in appearance, but in some cases they have had almost identical careers. The Gordon brothers, afterwards known as the "Gemini Generals," entered the army on the same day and both became full generals on the same day. Each became a K.C.B., and both were authorities and writers on affairs in India, where their military career was spent. Mr. R. C. Lucas⁸ describes identical twin brothers who entered as medical students on the same date and passed the examinations of the Royal Colleges and also of the M.B. of London University at the same time. In the intermediate examination the total numbers of marks obtained by the two brothers were the same. The records of their work were signed 33 times by 17 teachers, and in all the 66 records the only variation was that one brother was described as "excellent" and the other as "very good indeed." So that in the opinion of 17 teachers the abilities of the two brothers were identical. A striking example of equality in games was furnished by the Allen twin brothers, who for three years in succession represented Cambridge against Oxford at lawn tennis, and were also remarkably successful in many double events at the chief tournaments. In a different walk in life may be mentioned the brothers W., who were born in 1851, have worked together since 12 years of age, and for 34 years at the same steelworks. They were married on the same day, live in adjoining houses, and each has 10 children. Both are teachers in the Sunday school and are choristers. Galton¹ collected some striking examples of this similarity and the errors which may arise from one twin being mistaken for the other. In Galton's investigation, however, he found only one case in which the hand-writing of the twins was indistinguishable by themselves, and barely two or three in which no distinction could be made by others.

Twins may resemble each other in bad as well as in good traits as both may suffer from alcoholism. Curiously enough, in the case of Chang and Eng Bunker, the Siamese conjoined twins, one drank wine freely while the other did not, and this disparity in their tastes often gave rise to domestic strife. Chang, who had been hemiplegic for several years developed bronchitis at the age of 63 and died. Eng died two hours later.

ANATOMICAL SIMILARITIES.

The similitude of twins is found even in anatomical details. F. Sano⁹ who examined the brains of two still-born twins found them very much alike in structure. In the majority of pairs of twins both are either right or left-handed. Siemens² examined 45 pairs of identical twins and found 35 were right-handed and only one left-handed. In nine pairs one was right and the others left-handed. The characters of twins are often similar, so that they speak with the same inflection of voice and have the same dreams. They may have the same ideas simultaneously though separated at the time; thus Galton mentions a case in which one twin, A, bought a set of champagne glasses in a town in Scotland as a surprise for his brother, B, who at the same time bought a set of exactly the same pattern in England as a present for A. The similarity between twins is not confined to the obvious and easily recognisable features, but extends even to the fine structure of the friction-skin patterns of the palms and soles which may be almost identical. Gauthier and Rominger (Abt) found that there was a marked similarity in the finger prints and in the arrangement of the lines of the hands of five pairs of uniovular twins, whereas in the case of 42 pairs of binovular twins there was not the same striking

correspondence in the appearance of these lines. Symmetrical reversal is of much interest as it involves transposition of the viscera in conjoined twins. This reversal, though rare in separate twins, may appear in the finger prints which may be identical in outline but reversed, as in the case of the index fingers of identical twins observed by H. Wilder.¹⁰ As might be expected, various forms of congenital malformations have occurred in both twins. Among these may be mentioned spina bifida, cleft palate and lip, pseudo-hermaphroditism, excess of fingers, cerebral hernia, hypospadias, and hypertrophy of the umbilicus. In most cases the twins are almost certainly uniovular. Congenital defects also occur in only one of twins, which are then probably of the binovular variety.

The birth of twins is regarded as a misfortune by some races and as a blessing by others. In Matabeland it was attributed to the influence of evil spirits and so both twins were destroyed at birth. The Masai welcome twins, and in another tribe a special string of beads was given to the mother in honour of the occasion.

MORTALITY OF TWINS IN EARLY LIFE.

Twins are subject to a high rate of mortality in early life. Of 3883 pairs of twins in the Moscow Infant Asylum, 62.9 per cent. died during the first few weeks of life. In half of these fatal cases both died on the same day, and in the remainder one only survived the other by a few days. After the first few weeks the highest mortality occurs in the first two years. After the fifth year the mortality of twins appears to be the same as that of other children. Dentition does not necessarily occur at the same time and may be as much as four months later in one twin than the other. Twins may live to an advanced age. The D. brothers were both alive at 81 and had worked as pilots until the previous year. The G. brothers were well and active at 91, and there is a record¹¹ of an inquest which was held on a woman who was a centenarian at which her twin sister gave evidence of finding the deceased lying dead on the sofa when she returned from market. From what has already been said as to the remarkable similarity of physical and mental characteristics of homologous twins, it is not surprising to find that certain deviations from normal health are apt to occur in such twins at or near the same period of life.

HEREDITARY DEFECTS AND DISEASES IN TWINS.

The development of a disease in "similar" twins is strong evidence of it being due to some inborn or hereditary defect, whereas the occurrence of a malady in one twin and not in the other is in favour of it being due to some extraneous factor. Even during the first few days or weeks of life twins are liable to suffer from the same maladies. Thus Abt¹ mentions two boys who had simple pemphigus and two others who both developed left-sided mastitis followed by erysipelas. He also records the case of twin girls, aged 9 weeks, who both suffered from convulsions, well-marked tetany, and rickets. Abnormalities in metabolism may appear in either homologous or heterologous twins; thus Sir Archibald Garrod¹² mentions that five twin births have occurred in the known alcaptonuric families, comprising 112 recorded cases. In three of these the twins were binovular. In two pairs one twin was normal, and in the other three it is probable that only one was affected. Although alcaptonuria is a familial disorder it is notable that in no case were both twins alcaptonuric. In the pedigrees of 1000 albinos Sir Archibald Garrod found 29 records of twins, one or both of which were albinotic. In 11 pairs both were albinos, and 10 of these were of the same sex and so may have been homologous. In the case of cystinuria the same authority refers to two pairs of male twins observed by Colm and by Kietschmer, all of whom were cystinuric. My attention was first drawn to this subject by the occurrence of diabetes mellitus in twin sisters. One of this pair consulted me because she

had noticed an increase in the amount of urine she was passing. She stated that her twin sister, to whom she was greatly attached, had developed diabetes mellitus about a year previously. The disease had run a rapid course and ended in coma at the end of nine months. The development of the diuresis in her own case had made her apprehensive. When I first saw her the urine was free from sugar, but she returned after an interval and was then found to be suffering from well-marked diabetes. The disease ran just the same course as in the twin sister and she also died in coma at the end of nine months. Michaelis has recorded another example in the case of twin brothers of 60, who, living in different surroundings, both developed at the same time paræsthesia of the legs, perforating ulcer of the toe, diabetes, and albuminuric retinitis, and died within a few weeks of one another. These observations tend to support the view that in some cases of diabetes there is an inborn liability to failure of the islets of Langerhans, which may, however, occur early or late according to the habits and circumstances of the patient. In any case, it behoves us to take special precautions when diabetes appears in one twin to save the other from any undue strain on his sugar metabolism by unsuitable diet. Galton mentions the case of twin brothers who were similar in appearance and tastes, both obtained Government clerkships and lived together. One developed Bright's disease, which proved fatal, and the other died of the same malady seven months later.

MENTAL DISEASES IN TWINS.

As twins are similar in mental characters in health it is not surprising to find that they are liable to suffer from certain forms of mental and nervous disease, due in all probability to some inborn mental defect. This liability was shown by similar twin sisters observed by Marandon de Montyel.¹³ They began to menstruate the same day, and suffered from identical forms of the following maladies at the same time—colds, intestinal disorder, measles, mumps, and chicken-pox. They married and became pregnant at the same time, and in the fourth month of pregnancy each suffered from acute mania with identical religious and erotic hallucinations. The children, born within 48 hours of each other, were both boys. Both mothers rapidly recovered. Mongolian idiocy is a congenital defect, the true pathology of which is unknown. It is therefore highly significant that this condition may occur in uniovular twins. Dr. A. Strauch¹⁴ records an example of twin male mongols with typical features of the malady. On examining the literature he was only able to find two other examples of mongolism in both twins of the same sex, those recorded by Hjorth and by De Bruin, whereas in 17 cases only one was a mongol. As far as could be ascertained, it seems probable that the three former examples were uniovular twins, and all the others binovular in origin. Dr. W. H. Coupland¹⁵ mentions the case of twin sisters, aged 11, one of whom was a typical mongol, and the other normal. The rarity of mongolism in both twins is remarkable. When it occurs in one twin it may be due to the pair being binovular in origin, or it may be due to some defect which is present in only one of two spermatozoa fertilising a single ovum. Under the name of "La Folie Gemellaire" Soukhanoff¹⁶ collected 29 cases, and described another, of primary dementia in twin brothers. In these the insanity hardly ever developed simultaneously. Some became affected within a short period of each other, but in the others, varying periods of time, up to as much as 12 years, elapsed between the onset of the symptoms in the brothers. When one of a pair of twins becomes insane, it is most important to keep the other under observation so that any early symptoms of mental disorder may be treated at once. Sir Thomas Clouston¹⁷ records an example in which one brother was insane, but prompt treatment of the premonitory symptoms which appeared in his brother averted any further development of mental disorder.

SIMILAR AND SIMULTANEOUS ILLNESSES IN TWINS.

Whatever view we may take of the nature and causes of asthma, there can be no doubt that a familial predisposition is an important factor in many cases. It is not surprising to find that similar twins are both affected, as in the case of two brothers who always suffered from asthma at Marseilles, but were free from it at Toulon. Both suffered from rheumatic ophthalmia at the same time, even if they were at different places (Trousseau).¹⁸ The simultaneous onset of illness in twins is of much interest, as it may occur even when they are separated. Laycock²⁰ mentioned the case of the twin brothers Lautand who were nurses at a hospital in Bordeaux, who were always ill together and became affected with cataract at the same time. I have been informed of another example of this in the case of twin brothers living in different parts of Europe who both suffered from empyema at the same time. So also with migraine, as C. Gill¹⁹ observed twin sisters who suffered from headache and biliousness at the same hour, though they were at different places. They both became insane at the same time.

In some diseases of the blood and lymphatic glands of unknown causation we find examples occurring in twins, which is suggestive that some inborn error is an important factor in their origin. Dr. G. Peacocke²¹ described two cases of Hodgkin's disease in twin brothers at the age of 4. One died 18 months after the glandular enlargement first appeared, the other was still alive at the time of the report. Siemens² mentions an example of splenic leukaemia in twin sisters recorded by Senator. In hæmophilia it may be mentioned that in the well-known Yeadon family, recorded by Legg²² there were twin brothers who were both bleeders. This, however, is hardly surprising in a family in which male bleeders have appeared for the last 200 years. The development of tumours, either innocent or malignant, in twins appears to be a rarer event than might be expected. Halliday Groom recorded the cases of two sisters who first menstruated on the same day and from 30 years of age suffered from menorrhagia until the menopause at 50. At 53 both suffered from adenocarcinoma with myoma of the uterus. Siemens refers to two twin sisters observed by V. Szontagh, who at the same time developed papilloma of the larynx with identical symptoms. Davis²³ has recorded an example of congenital hypertrophic pyloric stenosis in twin boys. The Rammstedt operation was done in both, and a year later they were awarded the first prize for twins at a baby show. He refers to another similar pair of twins reported by H. L. Moore in which the same operation was carried out at the age of four weeks, but both died.

Goitre has been observed simultaneously in both twins but does not appear to be common. Siemens² refers to uniovular goitrous cretins observed by Hanhart. Twin brothers⁴ with goitres but no symptoms of myxœdema, and also twins of myxœdematous appearance were recorded by Petschacher.²⁴ With the exception of the cases of diabetes already referred to, I have seen no cases of any disease of an endocrine gland in both twins.

SUMMARY.

The evidence here considered shows that similar twins not only closely resemble each other in appearance and character but also in the finer details of structure and metabolism. This similarity renders them liable to suffer from those diseases which are due to some inborn error which sooner or later indicates its presence by definite symptoms of disease. Conversely, those diseases which are found to occur in both twins are most probably due to an inborn error rather than to external circumstances. It is therefore important to remember that where such a malady develops in one of similar twins it is not unlikely to develop in the other. The healthy twin under these circumstances should be watched and any possible steps taken to prevent the onset of the same malady, or at any rate to treat it in its earliest stage.

Milroy Lectures

ON

EPIDEMIC DISEASES OF THE CENTRAL NERVOUS SYSTEM.

Delivered before the Royal College of Physicians of London on March 5th, 10th, and 12th, 1925,

By ARTHUR SALUSBURY MACNALT, M.A.,
M.D. Oxf.,

A MEDICAL OFFICER OF THE MINISTRY OF HEALTH; EXAMINER
IN PUBLIC HEALTH IN THE UNIVERSITY OF OXFORD.

LECTURE II.*—EPIDEMIOLOGY OF CEREBRO-SPINAL FEVER AND OF ACUTE POLIOMYELITIS.

I.—THE EPIDEMIOLOGY OF CEREBRO-SPINAL FEVER.

History.

For a knowledge of the history of the epidemiology of cerebro-spinal meningitis up to the year 1886 all writers upon the subject are indebted to the authoritative and exhaustive article by Hirsch¹ in his "Handbook of Geographical and Historical Pathology." Hirsch groups the epidemic prevalence of the disease into four periods. The recent epidemics may be regarded as constituting a fifth period, according to Osler² and other authorities. In the first period, from 1805 to 1830, the disease occurred in isolated epidemics in various European localities and more generally in the United States. The second period was from 1837 to 1850 when the disease prevailed in widespread epidemics chiefly in military centres in France, Italy, Denmark, Algiers, and the United States. The third period lasted from 1854 to 1875. In this period the disease was widely prevalent throughout the greater part of Europe, in parts of Asia, in the United States, and in parts of Africa and South America. The fourth period, from 1876 to 1886, was denoted by a return to isolated epidemic outbreaks in various portions of the world, while the fifth period, beginning in 1896 and extending to the present day, has exhibited extensive and widely diffused major epidemics.

* Lecture I. appeared in THE LANCET last week. Lect. III. will appear in a subsequent issue.

Cerebro-spinal Fever in Great Britain.

Doubtful outbreaks occurred at Dartmoor in 1807 and at Sunderland in 1830, but the disease is not recognised generally as having appeared in Great Britain until Hirsch's third period.

In 1865 groups of cases were reported from several English districts, including London and Rochester; in 1866 a small outbreak of epidemic meningitis occurred at Bardney, near Lincoln. Infection may have been conveyed by reapers from Ireland. From 1887 to 1905 scattered outbreaks were noted from time to time. During this period a series of ten fatal cases came under the notice of Ormerod³ at St. Bartholomew's Hospital, details of which he published in THE LANCET during March, 1895. From 1902 to 1911 outbreaks occurred in Sussex, Lincolnshire, Northamptonshire, and Cambridgeshire.⁴

In 1912 the notification of cerebro-spinal fever became compulsory in England and Wales. From the end of 1914 to 1918 cerebro-spinal meningitis was epidemic on an unprecedented scale in this country. The epidemic synchronised in onset with the importation of cases of cerebro-spinal fever by the Canadian troops, the first cases occurring on Salisbury Plain where these troops were encamped. According to the report of the Medical Research Council's special advisory committee, the Canadians did not import a new disease, but they did introduce a virulent strain of the meningococcus, and were in some degree responsible for its spread. Infection was widespread, but the greater number of cases of the disease were notified in the Eastern and South-Eastern parts of England, where the majority of the troops were stationed. The general distribution of troops, therefore, appears to have influenced the prevalence of cerebro-spinal fever.

During the war epidemic (1914-18) 6450 cases of cerebro-spinal fever were notified in England and Wales. According to Reece,⁵ 4238 military cases of cerebro-spinal fever occurred in this country during the same period.

It will be seen from Table I. (Lecture I.) that the notifications of cerebro-spinal fever have declined without intermission since the year 1917, and the figures for 1923 are the lowest on record; with the passing of war and post-war conditions the incidence of this disease has now returned to normal. Scotland and Ireland suffered during the years of the war epidemic.

Geographical Distribution and Incidence.

Cerebro-spinal fever occurs in nearly all quarters of the inhabited world, being, perhaps, rather more prevalent in the temperate zone of the Northern Hemisphere.

The incidence of cerebro-spinal fever in any given population is necessarily dependent upon whether or not the estimation is made during a period of epidemic prevalence. The non-recognition of mild and abortive cases, classed otherwise as febriculae or "influenza," influence also the estimation, as in the allied examples of poliomyelitis and encephalitis lethargica. As a rule, the disease in large cities does not attack much more than 1 to 2 per 10,000 of the population.⁶ This is a much smaller morbidity-rate than that of measles, scarlet fever, diphtheria, and pneumonia in non-epidemic periods. The incidence of cerebro-spinal meningitis itself on the general population in non-epidemic periods is naturally extremely low. The attack-rate per 1000 of the population in England and Wales for the three years 1919, 1920, and 1921 was only 0.011.

Incidence in Urban and Rural Communities.

The stress of cerebro-spinal meningitis falls upon urban dwellers. In an epidemic year 1917, 347 cases occurred in London, 844 in urban, and 202 in rural districts. The increased incidence of the disease in urban communities seems not only to be due to the greater aggregation of persons in these communities with increased opportunities for acquiring infection, but is also associated with unhygienic

conditions and overcrowding, infringements of sanitary laws which prevail chiefly in towns and cities.

Mortality.

The mortality of cerebro-spinal meningitis varies considerably not only in different epidemics but also according to the age of the patient attacked. Koplik's⁷ statistics for children admitted to Mount Sinai Hospital show that the mortality in non-epidemic times is less severe than in epidemic periods, 38 per cent. in the former case as compared with 50 per cent. in the latter. In the two epidemic years, 1917 and 1918, the fatality-rates per 100 cases among the civil population in England and Wales, including London, were 65.4 and 67.6 respectively, but it is probable that many cases were not notified.

In Table I. (Lecture I.) the number of cases of cerebro-spinal fever notified in England and Wales from 1913 to 1923 are given, and the number of deaths from 1915 to 1923 in the civil population, but through the neglect to notify cases it is clearly valueless to calculate the fatality-rates with any degree of statistical satisfaction. It will be observed that in 1921 the number of deaths (414) exceeded the number of notified cases (411). The Glasgow ten-year rate of 72 per cent. may be regarded as a fairly average fatality-rate in an epidemic period. Higher and lower rates may occur. The epidemic in Sweden, which lasted from 1854 to 1861, is an example of a comparatively low fatality-rate; it was only 35.9 per cent.

In the early stages of an epidemic fulminating and fatal cases incline to prevail, while in the late stages mild and recoverable cases are more numerous. As Rolleston⁸ has shown, experience in the Navy testifies to the beneficial influence of serum in diminishing the mortality of cerebro-spinal fever.

Age, Sex, and Race.

The age of the patient has an important influence upon the mortality of cerebro-spinal fever. The mortality is heaviest among children under 2 years of age (over 80 per cent.) and in adults over 40 years, in the one extreme when the resisting powers of the body are imperfectly developed, in the other when these powers are not in their maximum force and vigour. From 2 to 15 years the mortality-rate tends to diminish—with the exception of a slight fall between 20 and 30 years the mortality rises again, the increase being marked after 30 years and increasing to a maximum with each successive ten-year period. In posterior basic meningitis, the special type of cerebro-spinal meningitis in children, which is most often seen between the ages of 4 months and 2½ years, but may occur up to the age of 5 years, the mortality is over 75 per cent. (Lees and Barlow⁹). Alike in epidemic and non-epidemic periods, the greatest incidence of cerebro-spinal fever falls on children under 15 years of age.

Cerebro-spinal fever on the whole affects both sexes nearly equally. There is, perhaps, a greater tendency for males to be affected. In Texas in 1912, of 2575 cases, 1598 were males and 977 females. In the epidemic of the war years males were chiefly affected. In the civil population of England and Wales the percentage of males affected was 51.4 in 1917 and 53.4 in 1918. The addition of the military cases notified in these years would materially swell the incidence of the disease on males. The male death-rate is often slightly higher than the female death-rate. In 1917 male deaths constituted 53.2 per cent. and in 1918, 56 per cent. of the total deaths.

Race and nationality, with the possible exception of the Negro race, which has been visited with particular severity in certain of the American epidemics, appear to exercise no predisposing effect upon the incidence of cerebro-spinal fever. Sophian¹⁰ has noted certain racial differences in epidemics, but it is probable that social status, overcrowding, and unhygienic surroundings are more responsible for them than any true racial incidence.

Season and Meteorology.

Epidemic cerebro-spinal meningitis is essentially a disease of the winter and spring months of the year. Approximately 80 per cent. of the epidemics occur in the winter and spring months. The majority of recorded epidemics have begun within one of the four months, December, January, February, and March, the maximum intensity of the epidemic being attained in April or May. From May the epidemic steadily declines and usually terminates by the end of July.

Similar features were seen in the epidemic in England and Wales in the years of the war. The period of maximum seasonal prevalence of the disease was in the early months of the year, and the greatest number of cases recorded in any one week in 1915 was in the first week in March, and in the years 1916 and 1917 in the fourth week in March. In the three years 1915-17 the rise and fall of the curve was steep although the fall was less abrupt, and in each year there was a preliminary rise in December. In 1918 the seasonal rise in the early months of the year reached its summit in the second week in February, and was less acute and the peak of the curve was less marked than in the previous years. Many cases occurred among the troops, and Reece⁵ has pointed out that the conditions of training and hut occupation in the early months of the year favoured the dissemination of infection acquired through the naso-pharynx. Glover¹¹ has shown that overcrowding is a more potent factor than season in favouring the incidence and carrier-rate of cerebro-spinal fever.

Whilst it must remain true that unusually cold weather is often associated with epidemics and with their highest peak in the epidemic curve, the occasional anomalous association with warm climates and warm weather is probably best explained by sudden marked temperature changes to which a particular community is not accustomed, and which cause widespread nasopharyngeal catarrh.

Sanitary Conditions.

Overcrowding, when it occurred in billets, hutments, and barracks during the Great War, undoubtedly favoured the spread of cerebro-spinal fever among the troops. It not only provides increased opportunities for contagion to spread from case to case, but it is invariably associated with lack of free ventilation which is another important predisposing factor. Multiple cases occur in households and are due to personal infection. Owing to the low vitality of the meningococcus outside the body it is unlikely that infection persists in dwelling-houses or in fomites.

Occupation and Fatigue.

The incidence of cerebro-spinal fever on troops has been repeatedly mentioned. The disease may be termed the camp-follower of war. That the chief cause of the enhanced incidence on troops is personal infection in populous urban centres is seen from the rarity of military epidemics in the field. The incidence of the disease in the Royal Navy during the war furnishes a parallel example. Rolleston¹² records that out of the 417 cases of cerebro-spinal fever in the Navy during the first three years of the war, 310, or 75 per cent., arose in the large depôts at Portsmouth (110), Plymouth (94), the Crystal Palace (59), and Chatham (49), while only 42 cases, or 10 per cent., were reported from sea-going ships. Jehle¹³ recorded outbreaks of cerebro-spinal fever in Silesia and Westphalia with a high incidence upon coal-miners and their families. Physicians and nurses sometimes contract cerebro-spinal fever in the course of their attendance on the sick, but the number attacked is not high.

By most authorities previous *fatigue* is recognised as a condition predisposing to cerebro-spinal fever. In a series of military cases (1914 to 1918) recorded by Worster-Drought and Kennedy,¹⁴ over 84 per cent. of the cases were in men of under one year's army service, that is among young recruits who were

unaccustomed to the strain of their new duties. Clinically, in epidemic periods it has often been recognised that undue mental or physical fatigue in individual cases predisposes to an attack of cerebro-spinal fever.

Previous Health.

With the exception of catarrhal conditions the previous state of health appears to exercise no predisposing effect on cerebro-spinal fever. The epidemicity among troops, usually men of superior physique, indicates that the healthiest persons may suffer from the disease in a severe form. The question of catarrhal conditions in cerebro-spinal fever calls for special consideration. Dopter¹⁵ recognised three stages in cerebro-spinal meningitis: (1) catarrhal, (2) septicæmic, and (3) meningeal, but this has not been borne out by the experience of Flack¹⁶ and Foster and Gaskell.¹⁷ The reports of the Medical Research Council indicate that in the opinion of the majority of the bacteriologists there is no causal relationship between catarrh and carriers of the meningococcus. Many cases of cerebro-spinal meningitis are unassociated with catarrh. It is now a usually accepted view that catarrhal affections of the respiratory tract, if preceding cerebro-spinal meningitis, are not due to the meningococcus, but favour the onset of the disease in epidemic periods.

Incubation Period.

In one's own experience in both military and civilian outbreaks in 1915-16, the usual incubation period appeared to be from three to four days. I have notes of two fulminating cases of cerebro-spinal fever in which the incubation period, so far as one was able to judge, appeared to be as short as 24 hours, a period which coincides with Sophian's minimum incubation period. Worster-Drought and Kennedy,¹⁸ reviewing the available evidence on the incubation period of cerebro-spinal fever, conclude that this period varies between 24 hours and seven days, its average duration being four days, and most authorities would agree with this opinion. With carriers who subsequently develop the disease the incubation period must of necessity be extremely variable. Flack¹⁶ adduces evidence to show that carriers may develop the disease at almost any time up to six or seven weeks after infection with the meningococcus.

II. EPIDEMIOLOGY OF ACUTE POLIOMYELITIS.

History.

The first authentic description of poliomyelitis was given by Michael Underwood¹⁹ in a treatise on the "Diseases of Children," published in 1784. Underwood was a Licentiate in Midwifery of the College; he was a skilful accoucheur and attended the Princess of Wales in 1796, when the Princess Charlotte was born. He associated the disease with teething and termed it "debility of the lower extremities." In 1822 Shaw¹⁹ reported a few cases in a book entitled "Nature and Treatment of the Distortion to which the Bones of the Spine and Chest are Subject." He related the disease to weaning in infants. Dr. John Badham,²⁰ of Worksop, Notts, in 1835, described four cases of poliomyelitis in the *London Medical Gazette*. The title of his paper was *Paralysis in Childhood: Four Remarkable Cases of Suddenly Induced Paralysis of the Extremities Occurring in Children without any Apparent Cerebral or Cerebro-spinal Lesion*. Badham for the first time drew attention to the cerebral symptoms presented by patients.

Jacob Heine²¹ (1799 to 1878) wrote a very instructive monograph on poliomyelitis in 1840, and is regarded generally as the pioneer contributor to modern knowledge of the disease. Heine was the first to recognise poliomyelitis as a disease of the spinal cord. Further clinical cases were reported by British and French physicians from 1841 to 1863, but no study of the pathology was made until the last-named year, when von Reinecker and von Recklinghausen,²² in Germany, and Cornil,²³ in France, described the lesions in the anterior cornua and

lateral columns of the cord. Afterwards there was considerable controversy over the nature of the changes in the medical press of the day, Charcot maintaining the disease to be a primary atrophy of the spinal cord, whilst others held opposing views. Rissler²⁴ first investigated the histology of the acute forms, and his work has been followed up and completed by the studies of Harbitz and Scheel²⁵ (1907). Wickman²⁶ (1905 and 1910), Strauss²⁷ (1910), and Peabody, Draper and Dochez²⁸ (1912). The first adult case of poliomyelitis appears to have been described by Vogt²⁹ in 1859. This brings us to the period when the work of Medin and Wickman conclusively demonstrated the true character of poliomyelitis as an acute infectious disease. This modern work was considered in the first lecture and its record completes the historical account of the disease.

Poliomyelitis in Great Britain.

The following is a summary of the chief epidemics of poliomyelitis recorded in England and Wales:—

- 1897. Outbreak in Hertfordshire (W. Pasteur).
- 1904. Cases in London (F. E. Batten).
- 1908. Outbreak at Upminster (W. W. Treves).
- 1909. Outbreak at Bristol (G. Parker).
- Cases in London (L. G. Parsons).
- 1910. Outbreaks in Cumberland (Carlisle), Northumberland, Nottinghamshire, Leicestershire, Dorset, Gloucester, and York.
- 1911. Epidemics in Devon and Cornwall (R. J. Reece), Plymouth, Huntingdon, Bedfordshire, Suffolk, Yorkshire, Westmorland, Derbyshire, and Wales.
- 1913. Outbreaks in Barrow-in-Furness, N.W. Lancashire, and Westmorland (Macewen).
- 1917. Outbreaks in Esher and the Dittons Urban District and Epsom Rural District (MacNalty), Cambridge, and Cambridgeshire (Macewen).
- 1921—Further increase in notifications of poliomyelitis. Many local outbreaks are still unnoticed until the appearance of crippling after-effects.
- 1923.

Poliomyelitis prevails in Scotland, and outbreaks have been reported and studied by Byrom Bramwell,³⁰ Edwin Bramwell,³¹ H. Bruce-Low,³² and others. Since 1913 small outbreaks have been recorded in Ireland.

Geographical Distribution.

The most extensive epidemics of poliomyelitis which have hitherto been recorded have occurred in Scandinavia and in the United States. The classical survey of epidemic poliomyelitis throughout the world was made by Bruce-Low,³³ and for details of the epidemics in various countries reference should be made to his illuminating report in the annual report of the Medical Officer of the Local Government Board for 1915–16.

Incidence and Frequency.

It is difficult to form even an approximate estimate of the incidence of acute poliomyelitis upon the general population. Although notification of the disease has been in force since 1912 in England and Wales a considerable number of cases of the disease are never notified. In support of this statement, already made several times, the following instances occur to mind: In 1911, 268 cases of poliomyelitis were officially notified in England and Wales; but in addition to these notifications there were reported at least 330 more cases, making a total for that year of 598 cases that came in one way or another under observation.

In certain towns poliomyelitis is endemic yet the disease attracts little attention. In the county borough of Sunderland, which had, in 1911, a population of 165,295, paralysed children are brought year after year to the Sick Children's Hospital, where the true nature of the disease is recognised. In 1912 the hospital books showed that eight cases of poliomyelitis were treated; ten in 1913, nine in 1914, and 12 in 1915. The medical officer of health for the borough only received six notifications of poliomyelitis between September, 1912, and March, 1916. This non-recognition of poliomyelitis in the acute stage occurs in other countries. The New York epidemic of 1907 was practically not noticed until the acute stage was over, when the large number of cases applying to the dispensaries and to the

neurologists for treatment led to full investigation by the New York Department of Health.

Table II. gives the proportion per million of the population of poliomyelitis for the years 1916, 1917, and 1918 as worked out for the notified cases of the disease in those years.

TABLE II.—Incidence on Population of Poliomyelitis.

				Proportion per 1,000,000 population.		
				London.	Urban districts.	Rural districts.
1916	..	..		45.5	17.6	12.6
1917	..	..		12.6	9.8	11.6
1918	..	..		12.9	6.1	5.8

These figures are subject to the qualifications previously discussed and the same reservation must apply to the American figures. The incidence must be controlled by many factors, of which probably the most important are the intensity of the outbreak, the virulence of the causal virus, and the susceptibility of the population. In an "unsalted" community—that is, one previously unattacked by poliomyelitis—there will naturally be a much higher incidence than occurs in a community where previous attacks have eliminated susceptibles or protected the juvenile members of the population from subsequent attack.

Incidence in Urban and Rural Communities.

It is possibly of significant interest that in 1910 and 1911, when epidemic poliomyelitis was ascertained to be largely prevalent in England and Wales, the cases observed chiefly occurred in rural areas and in small urban districts. More recent figures show an increased incidence in urban communities in England and Wales.

Mortality.

The case-fatality of poliomyelitis varies in different epidemics. An average variation is from about 10 to 25 per cent. The variable case-mortality is chiefly dependent upon whether the mild and abortive cases of the disease are recognised or escape detection in the different epidemics. The case-fatality rates are probably lower than those usually given on account of the failure to detect mild cases. In the Surrey outbreak of 1917, in which many mild and abortive cases were detected, I found the case-fatality to be 7.1 per cent., which is within the limits assigned by Holt and other observers. Nevertheless, instances are on record where there was an unusually high mortality. Wickman, for example, in a small epidemic of 26 cases, recorded a mortality of 42.3 per cent.

Age.

Table III. showing for England and Wales during the year 1918 for certain age-periods the age distribution of 228 cases of poliomyelitis, the number of deaths, and the mortality per cent., indicates that for persons over 10 years of age the mortality from the disease is higher. In this table, however, the highest case-

TABLE III.—Showing for England and Wales During the Year 1918 for Certain Age-periods the Age Distribution of 228 Cases of Poliomyelitis, the Number of Deaths, and the Mortality Per Cent.

Age in years	Cases	Deaths	Mortality per cent.	Age in years	Cases	Deaths	Mortality per cent.
0-1	23	9	39.1	15-20	14	4	28.5
1-5	100	24	24.0	20-30	7	1	14.2
5-10	49	11	22.4	Over 30	8	3	37.5
10-15	27	10	37.0				

mortality is seen in persons under 1 year of age, and it is highly probable that many mild and abortive cases for the age-periods under 10 years were unnoticed. The cases at the higher ages are more likely to have been notified as they are more readily diagnosed.

Generally, as Table III. indicates, the largest proportion of cases occurs between the first and fifth year of life. In the New York epidemic of 1907 as high a percentage as 90.5 per cent. of the cases occurred during the first six years of life. It is not altogether certain whether the disease occurs in utero. Morton,³⁴ Batten,³⁵ and others have reported cases which they considered examples of intra-uterine infection. The disease not infrequently occurs within the first years of life, 23 of the 228 cases notified in England and Wales in 1918 fell within this age-period. Duchenne³⁶ reported a case 12 days after birth, Bramwell³⁷ one of 3 weeks of age, and Sinkler³⁸ two cases under 1 month of age. Ruhräh and Mayer³⁹ state that adults are affected generally to the extent of about 10 per cent. of the various epidemics, but in this there are great variations, at times the percentage being higher and sometimes much lower. The second year of life appears to be most constantly affected by poliomyelitis.

Sex and Race.

Of 228 cases of poliomyelitis notified in England and Wales in 1918, 118 were males and 110 females. As a rule there is not much sex difference in the incidence of poliomyelitis; the figures of almost all epidemics agree in showing a slightly greater proportion of males than females attacked. In the New York epidemic of 1916 boys were 55.8 per cent. and girls 43.7 per cent. of the total.⁴⁰ Caverly⁴¹ reports males 57 to 60 per cent. and females 43 to 40 per cent. The proportion of males attacked seems to be higher in later life. Ruhräh and Mayer³⁹ observe that the disease is more liable to be severe in boys and the mortality-rate somewhat higher.

The factor of race does not appear to play an important part in the problem of susceptibility to poliomyelitis.

First and Second Attacks.

As a rule one attack of poliomyelitis produces permanent immunity. A few anomalous examples have been recorded by Medin, Leegaard, Auerbach, Neurot, Forster, Schwartz, and others in which there was recovery from an acute attack of poliomyelitis, and after an interval of several weeks or months the disease recurred with increased paralysis. Possibly this condition may be due to a re-activation of the original virus rather than to a subsequent re-infection. There are exceptional and rare cases in which a definite second attack of poliomyelitis has occurred in the same individual. Two cases of the kind occurred in the New York epidemic of 1916. Eshner⁴² has reported the case of a girl in which 11 years elapsed between the two attacks. Sanz⁴³ records a similar case with 14 years' interval.

Seasonal Prevalence and Meteorology.

There is a well-marked seasonal prevalence for poliomyelitis. It is noteworthy that the disease occurs more commonly in temperate than in warm climes, yet in the northern hemisphere it is most prevalent in the warm months of the year—namely, July, August, and September—though it may linger on during other parts of the year. In America Sinkler³⁸ studied 270 cases and found that 78.8 per cent. occurred from May to September, the dry months of the year. Poliomyelitis may indeed occur in any month of the year either in sporadic or in epidemic form, but the majority of the cases as indicated arise in the late summer and early autumn. The fewest cases occur in the winter and early spring. Epidemics in the cold months of the year are not unknown.⁴⁴

Transmission of the Disease and Consideration of Possible Predisposing Causes.

Evidence previously considered has indicated that the main factor in the spread of poliomyelitis is personal contagion. Here may be mentioned other views as to transmission of the disease and certain predisposing causes.

Transmission by Insects.—There is experimental evidence that the virus of poliomyelitis may be transmitted from infected monkeys by biting insects (bed-bugs and the stable-fly, *Stomoxys calcitrans*), and that it may be mechanically carried upon and in the bodies of common house-flies. These experiments would not necessarily establish that this is a natural method of transmission. The seasonal prevalence of poliomyelitis corresponding to the season and maximum prevalence of numerous insects, the early appearance of poliomyelitis in rural areas, and the irregular spread of epidemics are epidemiological features which have suggested the agency of some insect in conveying the disease. In epidemics personally studied, many of the patients were found to have been bitten by flies and other insects. I have notes of a case with a bad fly-bite on the eyelid a week previous to the onset of poliomyelitis; a similar history of a mosquito-bite was obtained in another case. Many patients, on the other hand, gave no histories of being bitten by insects in epidemic zones. Returns made to the Central Health Authority for the year 1918 show that insect-bites were seen on 2.2 per cent., and not seen on 52.6 per cent. of the patients. There was no available information in regard to 45.2 per cent. of the cases.

Regarding the seasonal prevalence of poliomyelitis, as Frost⁴⁵ has observed, it is not so definitely limited to the warmer months as would be anticipated if the disease is transmitted by outdoor insects, such as mosquitoes or biting flies. It differs, for example, from the well-defined seasonal prevalence of yellow fever. The usual restriction of the seasonal prevalence of poliomyelitis to summer and autumn militates against the likelihood of transmission by the parasitic insects of man, bed-bugs, lice, and fleas. The facts chiefly opposed to this view are, first, the evidence relating to personal contagion; secondly, the small total incidence of poliomyelitis; and thirdly, the preponderating incidence of the disease on children. Insect-borne diseases do not usually affect children rather than adults. The favouring influence of warm temperatures may be exercised upon the virus of poliomyelitis itself when infecting human beings rather than upon an hypothetical intermediate host.

Other Possible Modes of Transmission.—There is no substantial evidence as to the conveyance of poliomyelitis by foodstuffs, dust, or sewage, and the English and American statistics indicate that the disease cannot be specially associated with uncleanness of the patient or of the patient's surroundings.

Incubation Period.

The duration of the incubation period is said to be variable. In the experimentally produced disease in monkeys, Flexner⁴⁶ found that the time elapsing between inoculation and the onset of paralysis is from three or four days to 33 days, the average being eight or nine days. A virus passed through several generations of monkeys becomes adapted to its new host, and has a more constant period of incubation than when it is first transferred to the monkey from man. This fixed virus regularly causes paralysis in from seven to eight days. In man the incubation period appears to be short and to range within the limits of two to ten days. Wickman considered the period as from one to four days, basing his opinion on the interval between the dates of onset of the disease in two members of the same family. The observations of Draper, Peabody, and Dochez²⁸ on cases of familial infection would lead to a similar conclusion if they had not felt that it was impossible to exclude simultaneous infections of two members of the same family from a common source. Indeed, neglect of this factor is a trap for the unwary in the study of epidemics of nervous disease. Further statements on good evidence concerning the incubation period have been made as follows: Muller,⁴⁷ between five and ten days—average one week; Flexner,⁴⁶ two days to two weeks or even longer; Kling and Levaditi,⁴⁸ two to three days; Currie

and Bramwell,³¹ four days or less. My personal observations, based on case to case infection in epidemic periods, would place the incubation period at from two to ten days, the average period being three to four days.

POLIO-ENCEPHALITIS.

The record of the epidemiology of poliomyelitis would be incomplete without some reference to the cerebral form of the disease termed polio-encephalitis. In this type the lesion chiefly or solely involves the upper motor neuron giving rise to spastic paralysis. Vizioli,⁴⁹ in 1880, noted the close relationship of certain cerebral palsies in children to the spinal form of poliomyelitis, but polio-encephalitis was first described and named by Strümpell⁵⁰ in a lecture at Leipzig in 1884. He also first affirmed that poliomyelitis and polio-encephalitis are only to be regarded as different localised manifestations of a specific disease. The cases initially described were 24 in number, all under 6, and 19 under 4 years of age. The majority of cases indeed occur in children, but adults may be affected. In Medin's original paper† 11 out of 14 cases were described with cerebral signs. This was exceptional. Wickman,²⁶ in the Swedish epidemic in 1905, did not see a single instance. No case was reported in the New York epidemic of 1907, in which 1000 cases were observed. Peabody, Draper, and Dochez²⁸ met with no cerebral cases in their study, and few cases were found in the New York epidemic of 1916. Zappert,⁵¹ in 555 cases, described five cerebral cases. Two cases were observed in the Norwegian epidemic of 1905 in Christiania.

There has been series of instances in which there was a combination of the flaccid and spastic paralysis. Such cases have been reported by Wickman, Pierre Marie, Oppenheim, Neurath, and others. Ruhräh and Mayer³⁹ quote Möbius, who has described a brother and a sister taken ill at almost the same time with a febrile affection. In one there was a spastic hemiplegia with choreiform movements; in the other, flaccid paralysis.

In the small outbreak of poliomyelitis in Esher and the Dittons Urban District and Epsom Rural District in 1917, two cases of the cerebral form, both in children, were observed. One was a case of facial paralysis (pontine type), the other an ophthalmoplegia. Both cases occurred in intimate association with ordinary cases of infantile paralysis. The rare cerebral cases are sometimes somnolent, and cases of epidemic stupor in children, similar to those described in the first outbreak of encephalitis lethargica by Batten and Still,⁵² were recorded by Peabody, Draper, and Dochez²⁸ in the New York epidemic of poliomyelitis. Speech changes‡ (notably in Medin's ataxic cases), nystagmus, tremors, choreiform movements, rashes, and other symptoms similar to those seen in encephalitis lethargica have also been described in polio-encephalitis.

It is only in a few cases that the lesions of polio-encephalitis have been described, although it is not uncommon to find scattered lesions in the brain in cases of ordinary spinal poliomyelitis. Harbitz and Scheel²⁵ made a microscopical examination of the brains from two cases of polio-encephalitis occurring in the Norwegian epidemic of 1905 and found the lesions present identical with those of acute poliomyelitis.

When encephalitis lethargica first appeared in 1918 the suggestion was made that the cases of "the new disease" were only examples of the cerebral form of poliomyelitis, but our investigations soon indicated that the differences were more real than the apparent resemblances. Polio-encephalitis is a rare disease; it may be apparently sporadic, but it also occurs in direct association with other forms of poliomyelitis in epidemic periods, and Strümpell's early contention as to the identity of the two forms has been amply

substantiated. I have notes of several isolated cases of polio-encephalitis which have occurred in places where endemic foci of poliomyelitis exist.

Since Jan. 1st, 1919, cases of polio-encephalitis in England and Wales have been separately notified from cases of spinal poliomyelitis. Table IV. shows the number of cases notified in the period 1919 to 1923, with the number of deaths in the years 1921, 1922, and 1923.

TABLE IV.—*Polio-encephalitis in England and Wales. Numbers of Notified Cases and Deaths.*

Year.	Cases.	Deaths.	Year.	Cases.	Deaths.
1919 ..	62	—	1922 ..	31	27
1920 ..	36	—	1923 ..	57	40
1921 ..	51	40			

It will be seen from Table IV. that the mortality from this form of poliomyelitis is a high one. From the evidence available the incidence of polio-encephalitis would appear to be higher in England and Wales than in America. I should imagine there are few neurologists in this country who have not encountered examples of the disease.

‡ In my opinion, however, the speech changes described by Medin and others are not identical with the highly specialised and characteristic speech changes seen in encephalitis lethargica.

THE SURGICAL TREATMENT OF DUODENAL ULCER.

BY CHARLES A. PANNETT, B.Sc., M.D. LOND.,
F.R.C.S. ENG.,

PROFESSOR OF SURGERY, UNIVERSITY OF LONDON; SURGEON
TO ST. MARY'S HOSPITAL, PADDINGTON.

THE more closely the investigation of the treatment of duodenal ulcer is carried out, the less grows the inclination to be dogmatic in the matter, or, indeed, to lay down any inviolable rules of practice. An unbiased study of the writings of the accredited leaders and directors of thought in medicine and surgery leads to a most perplexing attitude towards the subject, so that the investigator is inevitably thrown back upon his own resources of experience to guide him in the treatment of cases which come under his care.

The extremes of opinion, that duodenal ulcer should almost never require surgical aid, and that once a duodenal ulcer can be diagnosed beyond reasonable doubt, the treatment should *always* be surgical, do not come into question, for it is easy to refute both these statements. At St. Mary's Hospital the two extreme schools of thought do not exist. Many duodenal ulcers are treated medically, get well, and remain so. Thus, of 91 patients diagnosed as duodenal ulcer admitted to the hospital during the years 1920-23, excluding, of course, cases of perforation, only 45 came to operation. It may be argued that it is an unwarranted assumption to regard all these diagnoses as correctly made when no operation has been performed, but experience on the surgical side of this hospital amongst patients handed over from the physicians has shown that the diagnostic error is not so high as to invalidate the general truth of the statement that many duodenal ulcers get well in the medical wards under treatment which includes a dietetic régime, the exhibition of alkalies or of atropine, and always rest in bed.

Indications for Surgical Intervention.

In the Surgical Clinical Unit opinion has crystallised as far as this, that operative intervention is not undertaken as a rule unless the disease has lasted for a considerable time, has proved refractory to medical measures, or has endangered life by causing a hæmorrhage, although the symptoms may be of very recent origin. As a matter of fact, the ordinary man, the bread-winner of a family, does not submit to operative treatment, with its associated considerable interference with his work, until he has failed to get relief from medicine after one or more fair trials, and finds life becoming too burdensome and intolerable for him to carry on. The following case is a warning against resorting to surgery at too early a stage in the disease.

CASE 1.—The patient, a male, suffered from symptoms which suggested the existence of an ulcer of the stomach or duodenum, and was operated upon at a large London Hospital by a well-known surgeon in 1915. A careful search was made, but no lesion of the stomach or duodenum could be found. The surgeon had no choice but to close the abdomen, leaving its contents untouched. No relief followed, and the patient struggled on with recurrent attacks of increasing severity until forced again into the hands of the surgeon in 1923, when he entered the St. Mary's Surgical Clinical Unit. A skiagram now demonstrated a deformation of the duodenal shadow and a persistent fleck after evacuation. On opening the abdomen a large ulcer on the posterior wall of the second part of the duodenum, penetrating into the pancreas, was revealed, with much surrounding fibrosis. The affected part of the duodenum with the pylorus was excised and, as the stump was rather short, owing to the amount removed, it was sewn up, and the open end of the stomach implanted into the jejunum. The patient has not had a moment's pain since.

A similar case is reported by E. Nordman,¹ where a neurotic girl was explored most carefully without result, whilst one year later a callous ulcer was found in the duodenum.

The following case shows how large an acute gastric ulcer may be without giving any evidence of its presence on the outer aspect of the stomach.

CASE 2.—The patient, a man aged 66, was admitted to St. Mary's Hospital in 1922, having had two severe hæmatemeses, accompanied by mælena. He was given two blood transfusions and operated upon by one of the surgeons, a rapid gastro-jejunostomy being performed. No ulcer could be detected on a careful examination of the stomach, but suspicion fell upon the duodenum. The patient, an ex-sanguinated elderly man, died within 24 hours. Post mortem there was found a large acute ulcer of the lesser curvature of the size of half-a-crown, with sharply punched-out edges and no reaction in the outer coat of the stomach at all, although it had nearly perforated. It could not be felt before opening the stomach, even on the post-mortem table.

An ulcer that is confined to the mucosa alone may give no evidence at all of its existence on the peritoneal surface of the viscus, nor may it give rise to palpable induration. Such ulcers may heal or they may be in process of evolution towards the callous state. Operation at this stage is premature and perhaps unnecessary. It must be remarked here that the detection of an ulcer on the posterior wall of the duodenum is by no means always simple. Palpation must be carried out through the anterior wall of the viscus, and the posterior wall, where the ulcer lies, cannot always be exposed to inspection. No examination is complete unless the lesser omental sac is penetrated and a search made from within it. On several occasions when resecting the duodenum, a second ulcer has been revealed first, only when the stomach has been cut across and the duodenum turned over to the right.

Results of Gastro-Jejunostomy.

The consideration of surgical treatment in duodenal ulcer starts then from the assumption that the patient has received adequate medical advice and acted upon it without avail, or that his life has been put in jeopardy by a hæmorrhage, without perhaps

having had any pain at all. The real difficulty is met when the efficacy of gastro-jejunostomy in the treatment of duodenal ulcer comes under inquiry, for strikingly diverse opinions are expressed.

A number of years have passed since the pioneer work of Moynihan established gastro-jejunostomy as the routine operation, so reliable knowledge on the subject should be at our disposal. Moynihan himself finds that over 90 per cent. of his operated cases (gastro-enterostomy with infolding of the ulcer) consider themselves perfectly well, and that the incidence of jejunal ulcer formation is not more than 2 per cent.² J. Sherren, in 500 cases, found 92.6 per cent. well two or more years after operation, and declares that if patients go for two years without symptoms, they never develop them afterwards.³ A. J. Walton,⁴ in 114 cases, had 85.8 per cent. cures and 10.5 per cent. very much relieved. Turning now to America, we find equally good results recorded. D. C. Balfour⁵ investigated the end-results in 1000 patients, all of whom had been operated upon for more than 10 years; 88 per cent. remained cured and only 3.5 per cent. of recurrences are known to have happened. The operative mortality was less than 2 per cent.

These results wellnigh reach such perfection as we can ever hope to get in any serious surgical procedure, and were it not for expressions of discontent with the operation of gastro-jejunostomy from continental surgeons, we could complacently continue to carry out treatment along these lines until the advance of medicine put such knowledge into our hands as would lead to the elimination of surgery for these patients.

H. V. Haberer in 1915⁶ expressed himself as being by no means satisfied with simple gastro-jejunostomy. He related three cases where at intervals of 2½, 4½, and 9 years after operation callous duodenal ulcers were found unhealed on re-laparotomy. The same author again, in 1921,⁷ said that in 49 cases he had had very poor results from simple gastro-jejunostomy. Maier⁸ relates a case where on reopening the abdomen two years after the primary operation the two original duodenal ulcers were found unhealed, and there was a new one at the anastomotic margin. K. Borszeki,⁹ of Budapest, relates two cases who got relief for only 2 and 14 months, when pain and bleeding occurred in both, necessitating a new intervention. E. Nordman¹⁰ says the good results after simple gastro-jejunostomy are 70 per cent. J. Galpern¹¹ gives the end-results in 52 cases; 69.2 per cent. cured, 11.5 per cent. much improved. The bad results were 19.3 per cent. A. Wydler¹² asserts that the longer one follows up cases after operation, the smaller the percentage of cures will be, and P. Clairmont agrees with him in this.¹³ As has been mentioned, the experience of Sherren is quite different. Wydler's results from de Quervain's clinic are 69.6 per cent. cures in cases followed for 1-4 years, and 64.3 per cent. in those followed for 4-10 years. A most interesting report is made by D. Forsyth.¹⁴ His statistics are taken from a sickness insurance society whose members are all medical men. Of 33 cases, where the diagnosis was established by operation, no recurrence (1-12 years) took place in 58 per cent.

The reports quoted above emanate from clinics where, without exception, the level of surgical attainment is very high. It is certain, therefore, that there must be some obscure difference in the manner of evaluation of the results, which are obviously not strictly comparable. Under such circumstances it becomes necessary for each surgeon to inquire what results he can obtain under the conditions which are familiar to him in person. For this reason 29 patients who had had simple gastro-jejunostomy performed for duodenal ulcer during the years 1920-23 at St. Mary's Hospital were written to, and of these 26 replied. Eighteen of them (69.2 per cent.) are well, live ordinary lives, and eat ordinary food. A number of them wrote enthusiastically in favour of operative treatment.

There is no doubt that they derived immense benefit. Eight of them (30.8 per cent.) expressed themselves as dissatisfied with the result. One of them has died. He was a man of 44, who had had late pain after meals (1-2 hours) and vomiting with free intervals for five years. There had once been a hæmatemesis. At the operation there was an ulcer adherent to the gall-bladder. He only obtained very temporary relief from the gastro-jejunostomy, the pain recurring, though the vomiting was less. He went on like this for three years, when he had a hæmatemesis and melæna, from the effects of which he died. The others all have indigestion pains, and one of them has had a bleeding.

CASE 3.—The patient, a man aged 28, had no pain at all after meals, but suddenly, ten weeks before admission, fainted from a severe duodenal hæmorrhage. He was still very anæmic on admission. An X ray examination showed a hypertonic stomach, an 8-hour residue and an attenuated duodenal cap. At the operation on June 11th, 1923, there was found to be an ulcer of the first part of the duodenum anterior wall, ½ in. beyond the pylorus. Duodenectomy contra-indicated because of weak condition of patient. Posterior gastro-jejunostomy performed. His progress was satisfactory until Nov. 20th, 1924, when, without any previous pain, he had another severe hæmorrhage. He is still suffering from the resultant anæmia and is under medical treatment.

This series is a small one, but the cases were carefully recorded and in every instance the disturbing factor of indifferent technique can be definitely eliminated. The percentage of success agrees exactly with that recorded by Wydler in de Quervain's Clinic. A careful scrutiny of the clinical records does not give any assistance in selecting those cases which will and those which will not be cured by gastro-jejunostomy. It cannot be said, for example, that when an ulcer on the posterior wall is adherent to the pancreas it will refuse to heal by gastro-jejunostomy.

CASE 4.—A man, aged 26, had had four years' pain, occurring 1½ hours after food and vomiting. He only got relief for about two weeks at a time. The skiagram showed an asymmetrical pyloric canal, and an ulcer niche on the median side of the duodenal cap. At the operation there was an ulcer on the upper border of the bend of the duodenum, spreading backwards to the pylorus. Another larger ulcer, with a distinctly palpable crater, could be felt on the pancreatic wall of the second part of the duodenum. I considered duodenectomy to offer too much risk, because of the extent of the lesion and its surrounding fibrosis. A simple gastro-jejunostomy was performed. Now, 15 months later, he is quite well, has no pain, and can eat ordinary food.

On the other hand, it is probably true that the immobilised ulcers in this situation heal with greater difficulty than those on the anterior wall of the first part of the viscus.

Duodenectomy.

The experience recorded above is ample justification for a search for some other method of dealing with intractable duodenal ulcers surgically. Because gastrectomy had been shown to give such very much better results than gastro-jejunostomy in ulcers of the stomach, continental surgeons naturally turned their attention to the eradication of duodenal ulcers by excising the affected segment of the duodenum. This question was mooted at the 1914 German Surgical Congress in Berlin, but the general consensus of opinion was that the operation was too hazardous and impracticable. So the matter stood until 1916, when, curiously enough, in the midst of the stress of war, several surgeons attacked the problem and proved that duodenectomy above the entrance of the common bile and pancreatic ducts could, with care, be carried out, without too considerable risk to the patient. Finsterer, Haberer, and Clairmont were particularly associated with this work, and have published large series of cases.

Recently I¹⁵ have described the technique and recorded my first nine cases. The operation is a tedious one, is exacting of the time and patience of the operator, and has dangers of its own. The

first difficulty is the control of hæmorrhage. The duodenum is supplied by the pancreatoduodenal artery, whose trunk cannot be ligated, as the pancreatic circulation would be interfered with. It is therefore necessary to tie separately each short branch as it comes off the trunk and straightway enters the duodenal wall. This must be done exactly or the operative field will become obscured by blood. The next great difficulty is the very widespread fibrosis which occurs in the neighbourhood of a duodenal ulcer. It changes the lesser omentum into a thick callous mass, it glues the duodenal wall immovably to the similarly indurated pancreas, it renders the discovery of the whereabouts of the common bile-duct sometimes impossible. Withal it causes the duodenum to be shrunken up on itself and an approximation of the papilla of Vater to the pylorus to take place. On first inspection the operation frequently appears to be impracticable. The essential decision to make is whether normal duodenal wall can be reached at a point which is above the ampulla of Vater. E. Nowak declares that he has never seen a duodenal ulcer spread so far down as the opening of the ducts, and he was able in every one of 41 successive cases to excise the duodenum. But although it is exceptional, ulceration may sometimes extend as far down, and such unusual cases should be borne in mind. An injury to the pancreas may lead to fat-necrosis and sub-phrenic abscess. A great danger is injury to the common bile or pancreatic ducts. This question was studied by P. Clairmont.¹⁶ He collected cases where the accident happened. The result is often fatal, and recovery when it takes place occurs usually after a stormy convalescence and further surgical intervention. I have recorded one case where the accident occurred, but the patient recovered with very little disturbance. Seven months later this patient was in excellent health. The common bile and pancreatic ducts are drawn close to the duodenal wall by the surrounding cicatricial tissue. They can be avoided only by keeping the dissection close to the duodenal wall, and, where the ulcer floor is formed by the pancreas, incising around the margin of the ulcer, leaving the base untouched, in exactly the same way as a gastric ulcer often is separated from the same viscus. In completing the operation the stomach is cut across about 2 inches from the pylorus and the duodenum just beyond the ulcer-bearing area. A direct axial anastomosis is then made between stomach and duodenum, the larger lumen of the stomach being partly sutured to reduce its size to that of the duodenum. Sometimes it has seemed more advisable to close the duodenum and implant the cut end of the stomach laterally into the jejunum.

I have now performed duodenectomy 18 times, and have been able to do an axial anastomosis in 16 of them. The junction may be troublesome to effect, and in three cases so little duodenal stump was available that a simple continuous Connell suture alone was used on the posterior aspect.

The Results of Duodenectomy.

I have, perhaps, emphasised unduly the drawbacks and difficulties of following the direct method of attack in duodenal ulcer, but this is rather to be desired if it is proposed to substitute, as a routine, a procedure which is attended by greater danger than gastro-jejunostomy. Such advance in the treatment of the disease, if such it is, should be made with all caution. Obviously the matter must be settled, and it is held to be a function of the professorial units to undertake such work. With this object during 1923 and 1924, duodenectomy has been performed whenever it seemed a safe and proper procedure.

Thus, of 29 duodenal ulcers treated during this time, gastro-jejunostomy was performed in 11 and excision of the duodenum in 18. Gastro-jejunostomy was selected for two reasons: either because the lesion in the duodenum was not considered

extensive or serious enough to justify duodenectomy, or, on the other hand, the surrounding fibrosis was so great that doubt was felt of the possibility of obtaining unaltered duodenal wall for suture without encroaching upon the region of the papilla of Vater. That not simply the easy cases have been chosen for excision may be gathered from the fact that in the 11 cases in which gastro-jejunostomy was performed there was a posterior ulcer present in 4, whilst amongst the 18 duodenectomies there was a posterior ulcer present in 17, and in 12 of these 2 ulcers were found. Of the immediate results, it can be said that the post-operative course has been uniformly smooth as far as the abdominal condition is concerned.

There has been rather a high incidence in pulmonary conditions. Coughs have been somewhat frequent and very disturbing to the patient. This may be related with the length of the operation, for it takes about 2 hours to perform, and never under 1½ hours. On the other hand, the incidence of lung complications lately has been unusually high after all operations upon the upper abdomen. In one man whose case-history I have reported elsewhere, the common duct was accidentally divided. It was implanted with the severed pancreatic tissue into the open end of the duodenum. Jaundice occurred for a few days, but the patient soon recovered and was in the best of health seven months later. One patient died.

CASE 5.—A female, aged 47, had suffered from gastric trouble for over 20 years. She had attacks of sickness about every three weeks. There was but little pain, except actually when vomiting took place. She was an emaciated woman. The skiagram showed much delay in emptying of the stomach. Operation on May 21st, 1924. A bilobed ulcer was found on the posterior wall of the duodenum and an incompletely healed ulcer on the anterior wall. Duodenectomy was performed according to the usual technique. There was much fibrosis of the wall of the viscus, the lesser and the greater omenta. The duodenal stump was joined axially to the stomach, a single Connell's suture alone being employed behind. After the operation she suffered from rapid pulse and oedema of the legs, became very pale, so that it was supposed that internal hæmorrhage was occurring, though no confirmatory evidence was obtained. No abdominal signs. A blood transfusion was given, but the patient got weaker and died on the eleventh day after the operation. Post mortem the abdominal wound and the anastomosis had healed to naked-eye inspection, so that at first sight the stomach seemed to pass normally into the duodenum. There was a small acute ulcer 1 inch beyond the junction. The heart was small and atrophic, the myocardium pale and fatty. There were oedema of the legs and some clear fluid in each pleural cavity. Death was due to cardiac insufficiency. This is a mortality of 5.5 per cent. in the first 18 cases.

In considering the mortality of duodenectomy compared with gastro-jejunostomy, it must be remembered that not in all hands is that of the latter operation as low as 2 per cent. During the last three years I have had three deaths after simple gastro-jejunostomy, which may be recorded here.

CASE 6.—A male, aged 67, had gastro-jejunostomy performed for chronic duodenal ulcer on May 10th, 1922. The operation was not unusual in any way. The ulcer was a large one adherent to the pancreas. Very soon after the operation his lungs showed signs of broncho-pneumonia. On the 17th he had a sudden attack of dyspnoea, from which time he got progressively worse until the eleventh day after the operation, when he died. Post mortem: a small infarct of the left lung; broncho-pneumonia throughout both lungs. Anastomosis healed.

CASE 7.—A male, aged 42, had gastro-jejunostomy performed for pyloric obstruction and ulcer of lesser curvature on Oct. 26th, 1922. On the 29th he developed definite lobar pneumonia with signs on both sides. On the night of the 31st he became suddenly hemiplegic on the left side and died the next day—i.e., five days after operation. Post mortem: in the left lung there was extreme congestion of the upper lobe and grey hepatisation of the lower lobe; in the right lung there was congestion and oedema of the upper and middle lobes with grey hepatisation of the lower lobe. The stomach was hypertrophied, the pylorus thickened from fibrous tissue, a band of which connected it with the scar of an ulcer on the lesser curvature 1½ in. from the pylorus. The gastro-jejunostomy

was in normal process of healing. The brain and cord were covered by a thin layer of fibro-purulent material.

CASE 8.—A male, aged 60, on June 17th, 1924, had gastro-jejunostomy performed for a cicatrix of the pylorus following ulcer here. He had recently had severe pain and hæmatemesis. Convalescence proceeded quite smoothly until the twelfth day after the operation, when he suddenly sat up and died. Post mortem: there was a large ante-mortem clot coiled up in the pulmonary artery just at its bifurcation. There was a puckered scar at the pylorus and a large ulcer of the stomach which had been overlooked, situated in the cardiac region with one edge almost encroaching on the œsophagus.

Deaths such as these are extremely difficult to avoid in the present stage of knowledge, in spite of every care being taken in the preliminary examination, and the decision against operating should any signs of a lung affection be apparent. Deaths due to a fault in the technical abdominal procedure have been almost eliminated. It is fair to say, I think, from my own personal experience, that the mortality of duodenectomy will not in the long run prove very much greater than that of gastro-jejunostomy in skilled hands. V. Haberer¹⁷ reports 169 resections with a 3.5 per cent. mortality, and H. Finsterer¹⁸ had a 1.4 per cent. mortality only in his last 71 cases. This death-rate is about the same as the most favourable statistics of simple gastro-jejunostomy.

Of the late results I prefer to leave the consideration of my own cases until a further period of time has elapsed. The early after-history has been very favourable. Finsterer¹⁸ got 59 absolute cures after 3-5 years or longer in 63 cases (93.6 per cent.). In three other cases of this series the patients can eat anything, but occasionally get discomfort; one has heart-burn after heavy drinking, one has ventral hernia, and one lower abdominal pain of unexplained origin.

The future alone will show whether these very good early reports reflect what the result of the operation will be in the general surgeon's hands. Meanwhile, I think an open mind must be kept towards this subject. The operation appeals on physiological grounds, for there is less upset to anatomical relations and digestion if an axial union is performed.

Pyloric Exclusion for Irremovable Duodenal Ulcers.

There will always be some ulcers where the local conditions will forbid excision, the cases where, above all others, the operation is needed, where the ulcer is extremely large, unusually callous in nature, and deeply penetrating into the pancreas. It is such cases in which gastro-jejunostomy proves ineffective very often. V. Haberer could only obtain 37 per cent. cures by simple gastro-jejunostomy. Obstructing the pylorus at the same time (by cutting the stomach right across proximal to the pylorus, according to Von Eiselsberg's technique) has proved itself a satisfactory procedure in some cases and has given relief where a previous simple gastro-jejunostomy has proved ineffective. This combination of pyloric exclusion with simple gastro-jejunostomy has been carried out fairly extensively in some clinics, but the balance of opinion is against it, for a jejunal ulcer has been found to occur in 17 per cent. subsequently.

Such irremovable ulcers present, therefore, a very difficult surgical problem, and the only contribution to the subject is that of Finsterer, who asserts that pyloric exclusion with removal of half or two-thirds of the stomach is curative in these cases, and is not followed by jejunal ulceration. In 8 cases, 3-5 years, 7 remained cured, and 1 has had a subsequent cholecystectomy; of 15 cases, 1-3 years, 13 are absolutely well, 1 case has pain, and 1 has had a hæmorrhage. This subject requires further investigation.

Conclusions.

There can be no reasonable doubt that in the evolution of the treatment of duodenal ulceration

surgery is only a temporary expedient, but neither can it be denied that, in the present stage of knowledge, operative treatment is able to confer upon the sufferer that relief which medicine is unable to bestow. Gastro-jejunostomy is a method which effects a cure in about 70 per cent. of cases in the small series reported here. These results do not show the operation in as favourable a light as revealed by other statistics in this country and America, based on very large series, but they agree with those reported from continental clinics. The direct method of attack, as in the analogous gastric lesion, is likely to prove more effective in treatment if it can be carried out free from serious risk to the patient. In the cases of duodenectomy reported here the early results have been satisfactory, but the later clinical history of these patients remains for further study. This limited experience is favourable enough to justify a continued trial of duodenectomy in the treatment of duodenal ulcer.

I have to thank my colleagues on the staff of St. Mary's Hospital for their courtesy in allowing me to make use, for statistical purposes, of patients who have been under their care.

GLYCOSURIA, THE SYMPTOM.*

By WALTER R. CAMPBELL, M.A., M.D. TORONTO,
DEPARTMENT OF MEDICINE, UNIVERSITY OF TORONTO,
AND TORONTO GENERAL HOSPITAL.

THOUGH diabetes was named and described by Aretæus the Cappadocian, about A.D. 70, and was known to the Chinese as the wasting-thirst disease many centuries ago, its striking symptoms must have been encountered long before the era of recorded medical knowledge. The sweet taste of diabetic urine was mentioned by the Indian physician, Susruta, about A.D. 500, and by the Persian, Avicenna, about A.D. 1000. In Europe, however, it appears to have escaped notice until recorded by Thomas Willis in 1679, though its significance as indicating the presence of a sugar was not pointed out till nearly a century later by another English physician, Matthew Dobson. He also discovered that the blood, as well as the urine, of diabetics was sweet, that the latter underwent alcoholic fermentation on standing with a disappearance of the sweet taste, and that on evaporation of a quantity of diabetic urine a white mass tasting like brown sugar remained. His observations on the urine were soon fully confirmed by others, among them the Edinburgh physician, Francis Home. Chevreul, in 1815, showed that the sugar of diabetic urine resembled that derived from starch, but it was not until the year 1838 that Peligot furnished definite proof to the members of the Académie des Sciences, Paris, that the sugar of diabetic urine, of grapes, of honey, and that from starch are one and the same substance, and the name glucose was proposed for it ($\gamma\lambda\epsilon\upsilon\chi\omicron\varsigma$ —unfermented wine).

* A paper read at the Academy of Medicine, Toronto.

Reducing Substances in Urine.

Since then remarkable advances have been made in our knowledge of diabetes, both from the laboratory and clinical aspects. Largely through the introduction and use of simple tests for glucose in the urine it has been found that the symptom is present in a number of conditions other than diabetes mellitus, and also that other substances occurring in the urine in abnormal amounts or under abnormal conditions react to some of the tests like glucose itself. Such facts have added to our difficulties in the diagnosis of diabetes and merit further consideration.

In small amounts glucose is a constituent of normal urine along with minute quantities of other carbohydrates, principally pentoses, dextrins, and other polysaccharides. The term glycosuria should be reserved to designate the condition in which abnormal amounts of glucose (above 10 mg. per kg. body-weight) appear in the urine. Glycosuria then takes on something of a quantitative character, but it is important to realise that the most commonly used tests for glycosuria, the reduction tests such as Nylander's, Trommer's, Fehling's, Haines's, and Benedict's, do not diagnose glycosuria per se, but merely indicate whether or not reduction of the heavy metal—usually copper—from a highly oxidised form to a lower plane of oxidation has taken place. Other substances in urine besides glucose may cause this reduction, and different testing solutions will respond in very different degrees both to glucose and to other reducing substances—creatinin, uric acid, &c.—while the addition of certain preservatives, such as formalin or chloroform, may result in a factitious reduction and lead to errors in diagnosis. Further, it is often not realised that the concentration of electrolytes and organic matter in the urine as well as the presence of other pathological constituents, such as bile and albumin, excessive amounts of urobilin or indican, play a part in the reduction reaction, some in a positive, others in a negative direction. While under most conditions small amounts of inorganic salts in the urine tend to increase the sensitivity of the reduction test, in other cases reduced copper oxide is not precipitated but remains dissolved in the liquid. Particularly is it important that specimens being tested are not alkaline in reaction, as ammonia and ammonium salts hold cuprous oxide in solution. Creatinin also dissolves cuprous oxide. It is sometimes thought that slight reduction of the test solution by a urine of a very high specific gravity is evidence of glycosuria, but this is untrue. Whenever the high specific gravity is due to glucose the reduction will be intense. On the other hand, urinary specific gravities of 1006 are not inconsistent with moderate glycosuria, especially if the patient is on starvation treatment or is receiving large quantities of fluids.

Benedict's Test.

Most of the tests mentioned above, combined with experience in their use, may be made to yield satisfactory results, but the simplest and most valuable qualitative test for sugar is that of Benedict's,¹ as with it the possibilities of error are reduced to a minimum. Benedict's solution is so adjusted that the normal amounts of sugar in a urine of medium specific gravity are missed. In its use it must be remembered that the development of complete opacity to light, and not colour change, is the evidence of pathological amounts of reducing substances. The directions for the test must be carefully observed. Eight drops of urine are boiled two minutes over a free flame

¹ Benedict, S. R.: Jour. A.M.A., 1911, lvii., 1193.

Formula: Recrystallised copper sulphate	.. 17.3 g.
Sodium or potassium citrate	.. 173 g.
Sodium carbonate, anhydrous	.. 100 g.
Distilled water to make	.. 1000 c.cm.

Dissolve the citrate and carbonate in 700 c.cm. of water with heat. Filter if necessary and add the copper sulphate (dissolved in 100 c.cm. water) slowly with constant stirring. Cool and add water to 1000 c.cm.

with 5 c.cm. of the solution² and then set aside to cool. If, when shaken, the cold solution blocks out the image of the window bars or the filaments of the electric light, sugar is, in all probability, present. Occasionally a grey-green opacity, due to phosphates, occurs with urines of high specific gravity and also when albumin is present, or with urines of low specific gravity the test may be excessively sensitive. In either case dilution of the urine with an equal quantity of water before testing results in a negative test. Any quantity of glucose missed by such dilution is negligible from a clinical point of view. When a patient with marked polyuria is on a low calorie diet glucose may occasionally cause a reduction to the deep red cuprous oxide without producing complete opacity. On examining such a solution by reflected rather than transmitted light, a reddish opalescence is seen. Considerable amounts of sugar may be present under such circumstances, and when an apparently negative test occurs the test-tube should always be examined for traces of adherent red or yellow cuprous oxide. The further possible sources of error, if one regards a reduction test as significant of glycosuria, are somewhat infrequent and are due to the presence of other abnormal substances in the urine, such as lactose, homogentisic acid, melanin, pentose, or of glycuronates, in cases where certain drugs such as morphine, chloral, and coal-tar compounds have been administered.

The Fermentation Test.

In a few cases it is beyond the resources of the average physician's laboratory completely to identify the substance causing the reduction, and such questions may be left to those with a broader chemical training and greater equipment. It is of considerable clinical importance, however, to demonstrate that the substance is or is not glucose. While the history of the case may provide a high degree of probability in one or other direction it is much strengthened by the results of a properly performed fermentation test. In performing a fermentation test there are several points which should be carefully observed. About 1/16 cake of fresh yeast should be rubbed up with somewhat more of the urine than is sufficient to fill the closed arm of the fermentation-tube. The latter should be filled, carefully removing all air bubbles, and the tube set in a warm place for one to 24 hours, preferably in an incubator. At least two controls should be set up at the same time—one with yeast and water instead of urine to determine whether gas is formed from the yeast, and the other with a dilute solution of glucose (corn syrup) to test whether the yeast will ferment glucose. If the first control shows no gas formation in the closed arm of the tube and the second shows considerable gas the result of the test on the urine may be considered. Gas formation will occur providing the yeast is active, due to the fermentation of glucose and of urea. It is advisable, on account of the latter, to consider a urine showing less than 1 in. of gas in 24 hours as being free from pathological amounts of glucose. Larger amounts of gas after 24 hours' standing, or definite gas formation within an hour or so, are fairly good evidence of the presence of glucose in the urine. Absence of fermentation in a urine which has reduced Benedict's solution indicates the presence of some other abnormal substance, which may or may not be of pathological significance, and special methods must be employed for its identification. The commonest of these substances are lactose and glycuronates, and these may usually be diagnosed from a history of late pregnancy or lactation in the first case, and of the use of drugs in the second case. It may be of value to remember, however, that the commonest sugar encountered during pregnancy is glucose, not lactose, and that this glycosuria may be an accident (alimentary or renal glycosuria), or a pathological symptom of considerable significance.

² The tube may be placed in a vessel of boiling water for five minutes instead.

Causes of Glycosuria.

When it has been established that glucose is present in the urine, one must endeavour to find the cause. The possible causes are very numerous and here nothing helps quite so much as a well-taken history to clear up the diagnosis. Glycosuria may result from excessive intake of sugar (the so-called alimentary glycosuria), but this may be determined from the history and from the fact that the excretion of glucose is but temporary. In the anæmias and the toxic goitres, during starvation and under emotional stress, temporary glycosuria may also occur at intervals, the quantities excreted never being very large. Similarly, with a cerebral accident, such as hæmorrhage, thrombosis, or embolism, or with intracranial tumours, pituitary disease or concussion and fracture of the skull, slight transitory glycosuria occurs. These are accidents of carbohydrate metabolism, but, as these conditions may be accompanied by a starvation acidosis with acetone bodies in the urine, a mistaken diagnosis of diabetic acidosis or coma is sometimes made.

During septic infections, cholecystitis, acute and chronic pancreatic disease, and after prolonged alcoholism, more or less transient glycosuria may also be present. Under these conditions the differentiation from true diabetes mellitus may be particularly difficult, as the condition may clear up entirely or progress slowly into true diabetes. Such cases are best regarded as temporary diabetes as they are probably due to a functional degeneration of the islet cells of the pancreas, and the principles of treatment should be those applicable to diabetes mellitus—namely, rest to the pancreas by restriction of diet until the need disappears.

True diabetes mellitus is characterised by recurrent glycosuria over long periods of time. There need not be, and in the milder cases there is not, continuous excretion of glucose throughout the day. The most intense glycosuria follows the meals. The urine secreted during the early morning hours is often sugar-free. It has been stated that the diabetic cannot eat two normal meals without showing glycosuria, and this is true as far as it goes. However, in the milder cases of diabetes mellitus there are no clinical symptoms, excepting glycosuria, and thus diabetes is sometimes confused with certain other less common conditions which show glycosuria on such a test. These are: the renal glycosuria of pregnancy; renal diabetes in Klemperer's sense (benign glycosuria in a nephritic); idiopathic renal glycosuria; toxic renal glycosuria; and a group of cases intermediate between true renal glycosuria and diabetes mellitus, which may be called diabetes innocens.

Diagnosis of True Diabetes Mellitus.

Resembling as these cases do the less severe cases of diabetes in many particulars, it is of considerable importance for the patient's future that they should be accurately differentiated from true diabetes mellitus. Careful investigation of all cases of recurrent glycosuria should be undertaken to sort out these patients, since their prognosis is good and is not in any way improved by dietary restrictions. Indeed, they may reasonably be grouped with Garrod's "Inborn Errors of Metabolism," or perhaps, since they are not necessarily congenital in origin, they may be better designated as the anomalies rather than the diseases of carbohydrate metabolism. However, until sufficient evidence has been accumulated to justify freeing him from the diabetic regimen, the individual showing this anomaly should be treated as a diabetic patient. Certain characteristics are common to this group which help to separate it from diabetes mellitus. First, they are symptomless apart from glycosuria unless, perchance, they have previously undergone an excessively rigid dietetic régime, resulting in weakness and emaciation; second, they are usually discovered accidentally during routine physical examination: third, the

glucose percentage and total excretion of glucose in 24 hours is small; fourth, the glucose is unaccompanied by acetone bodies unless there are other causes for their presence, such as pregnancy or starvation; fifth, increased carbohydrate intake does not produce a commensurate increase in the glycosuria; sixth, the respiratory quotients after glucose ingestion rise to values around 1, indicating the normal utilisation of the carbohydrate; seventh, the condition shows no tendency to progress even under dietary conditions highly unfavourable to the true diabetic. Probably the most significant differentiating point, however, is the fact that in such cases glycosuria can be repeatedly shown to be present while the blood taken at the same time shows a normal sugar content.

By indirection, then, we arrive at a diagnosis of diabetes mellitus from the symptom glycosuria. It should be emphasised, however, that the symptom itself is of little importance other than as a diagnostic clue to a possible serious metabolic defect. Clinical and laboratory investigation during the last 40 years, culminating in the recent work on insulin, has shown that diabetes mellitus is due pre-eminently to a failure of the islet tissue of the pancreas to function normally. Carbohydrate metabolism is thereby impaired, hyperglycæmia results, and glycosuria occurs when the blood-sugar reaches an excessively high level. Treatment for the condition is not to be directed to abolition of the glycosuria, though this is an incident when treatment is successful, but to the provision of adequate rest to the pancreas from over-work, the maintenance of a normal blood-sugar level, and, at the same time, provision of sufficient calories to restore to the individual the ability to do physical work.

In conclusion, then, one would emphasise the necessity of carefully differentiating glucose from other reducing substances in the urine, and when glucose is actually present the importance of distinguishing between the accidents and anomalies of carbohydrate metabolism and the disease diabetes mellitus.

Clinical and Laboratory Notes.

A CASE OF SNAKE-BITE.

AN UNUSUAL INCIDENT IN SANATORIUM TREATMENT.

By H. O. BLANFORD, M.B., B.S. LOND.,

MEDICAL SUPERINTENDENT, PRIOR PLACE, HEATHERSIDE, CAMBERLEY.

THE following case occurred at the King Edward VII. Sanatorium, Midhurst, in the exceptionally hot and early spring of 1921.

The patient was a naval officer who had been sent home from Hong-Kong in March with signs of slight infiltration at both apices. His general condition was exceptionally good and the temperature normal and regular. He was therefore able to begin a course of graduated walking exercise almost immediately, and on April 1st I met him near the entrance coming in from his walk at 11.25 A.M. He was grasping the neck of a living viper, about 2 feet long, which had just bitten him. He had been sitting on a bank, and hearing a rustle among the dead leaves put his hand in to investigate, with the result that the snake bit him. He showed me a minute scratch on the skin between the heads of the metacarpals of index and middle fingers of the right hand. I had not previously seen a case of snake-bite, but was under the impression that the bite of an English viper was not likely to cause any grave anxiety.

I proceeded to scarify the skin round the scratch and to rub in potassium permanganate. While I was doing so the patient felt faint and vomited, but it was only when I found the radial pulse almost imperceptible that I began to realise the seriousness of the situation. This was at 11.45 A.M., half an hour after he had been bitten. The patient was at once taken to bed and rapidly grew worse. Diarrhoea began soon afterwards, and by 2 P.M. signs of marked collapse were present, face pallid, radial pulse absent, and temperature

subnormal. At 4 P.M. he complained of severe pain in the hand and forearm, and there was oedema reaching to the elbow. On the following morning, April 2nd, the condition was improved. The diarrhoea had ceased and there had been only one attack of vomiting. Pulse 100. The oedema had increased and spread upwards to the shoulder, and there was diffuse ecchymosis on the inner and posterior surface of the forearm. In the afternoon his condition again became worse, the face was pallid, and the lips cyanosed, the heart beats at apex were 112, with a pause at every third beat. Radial pulse was 84 and weak. He was given rectal and intravenous injections of saline and strychnine hypodermically. Next day his condition appeared critical. The arm was swollen to a great size, and the oedema had spread upwards as far as the angle of the jaw. There was pain on swallowing and also across the right pectoral muscles and scapula.

Mr. David Ewart, hon. consulting surgeon to the Sanatorium, kindly came up to see the case and made two incisions on the dorsum of the hand under chloroform. Serum was evacuated but no pus. After the operation brandy, half an ounce two-hourly, and strychnine, hypodermically four-hourly, were administered. Pulse 112, very weak, tongue furred, face flushed. Urine contained a trace of albumin, no blood. On the following day the condition remained about the same. The painful oedema and ecchymosis continued to spread over the back. On April 7th improvement set in, but the oedema and ecchymosis had spread to the buttocks and left hip. By the 9th the condition was much improved. The incisions were discharging serum freely, and the oedema and ecchymosis were subsiding. He made an uninterrupted recovery, and the pulmonary condition seemed in no way adversely affected. He was subsequently able to leave the Sanatorium at the completion of his treatment and to return to his professional duties.

Apart from the comparative rarity of snake-bite in this country, the interest of the case was enhanced by the casual manner of its beginning, and the unexpected rapidity and severity of its development.

A CASE OF TRAUMATIC THROMBOSIS OF THE VENA CAVA SUPERIOR: RECOVERY.

BY DR. L. VAN DER HOEVEN,
THE HAGUE.

"COMPLETE obliteration of the vena cava superior with the establishment of collateral circulation is extremely rare" (Osler¹). Syphilis, tuberculosis, and malignant growths in the anterior mediastinum are the most common causes, and complete obliteration by aneurysm is very rare. Although traumatic thrombosis of the vena cava inferior has been observed at autopsy, I find no record of this occurrence in the vena cava superior. Schepelman² has published a case of traumatic thrombosis of the left subclavian vein caused by excessive effort on horse-back, but I find no record of any similar occurrence in the medical literature of the war.

In view of the rarity of the condition the following case deserves record:—

A military officer, aged 53, was thrown from his horse on Feb. 8th, 1915, alighting on his back on a hard road. He was rendered senseless for some minutes, and, on recovering, complained of severe pain in his back and chest, and of shortness and oppression in breathing. Next day, feeling his collar tight, he noticed his neck swollen, and by the following day his face, neck, and arms had become enormously swollen and livid, the ears and tongue cyanosed, the eyes protruding, and the veins of the neck and arms dilated. On April 15th, 1915, the cyanotic swelling of the face persisted, the jugular veins and those of the arms being greatly dilated, but those of the thoracic wall were unaffected. There was no jugular pulse, and no oedema of neck or arms. Some dullness over the manubrium sterni was observed, and the cardiac impulse was feeble, but no other abnormality was evident. Wassermann reaction was 100 per cent. positive. He denied syphilis, and I had been his doctor for 40 years and never observed any syphilitic manifestation.

All this pointed to an obstruction of the venous return through the vena cava superior—was the cause pressure by aneurysm or mediastinal blood clot, or was it thrombosis?

¹ Obliteration of Vena Cava Superior, Johns Hopkins Hosp. Bull., xiv., 148, 1903.
² Monatsschr. f. Unfallheilkund., No. 3, 1911.

Thrombosis of the vena cava superior has been found post mortem with syphilitic aneurysm of the aorta, mediastinal gumma, malignant growth, or tuberculous mediastinitis. These causes were all ruled out, as the symptoms immediately followed the accident, and there was no antecedent history of ill-health. The diagnosis of thrombosis was therefore adopted.

On August 16th, 1916, the heart was found normal, and Dr. van der Haer was able to exclude aneurysm or syphilitic aortitis. The cyanosis slowly decreased, and collateral circulation through the superficial veins of the thorax and abdominal wall had become established.

There had never been cyanosis of the thoracic wall, and it was probable that circulation by the vena azygos (which joins the vena cava superior just above the right auricle) was free. The blood from the thoracic wall could thus pass by way of the intercostal veins to the vena azygos major, and by way of the long thoracic, epi-, and hypo-gastric veins to the venae cavales.

January, 1917: The superficial veins of the arms and jugulars are still dilated, although in less degree. When erect there is but slight cyanosis, but on stooping it becomes apparent, and it is impossible for him to lie flat because of oppression in breathing. He sleeps in bed with the head elevated. There is some dullness over the manubrium and in the second right intercostal space. The heart dullness is enlarged to the right, and the apex beat is nearly in the nipple-line. There is a weak systolic murmur at the apex. The blood pressure is 200 maximum and 100 minimum. Auscultation of the aorta points to the presence of arteriosclerosis. The W.R. is still strong positive. The heart thus is enlarged, and there is probably a relative mitral incompetence.

October, 1923: The superficial veins are less prominent, but he cannot bend or lie without oppressed breathing and cyanosis. Bicycling or brisk walking against a wind induces dyspnoea. The X rays show an enlargement of the heart in both directions, and there is no shadow of aneurysm.

December, 1923: Heart sounds weaker. There is probably dilated and hypertrophied heart with commencing myocardial degeneration. W.R. and Sachs-Georgi reactions positive.

Jan. 12th, 1924: I examined him with Dr. Lankhout, and we thought there was commencing aortic insufficiency, there being a faint diastolic murmur but no aneurysm.

May 20th, 1924: At this examination I could not hear the diastolic murmur; otherwise the condition was unchanged.

Cases have been recorded by several observers where obliteration and thrombosis of the superior vena cava were due to syphilitic mediastinitis and phlebitis. Syphilis is doubtless the main cause of chronic obliteration of the superior vena cava. Is the present a pure traumatic case, or was the interior of the vein weakened by a previous chronic endophlebitis syphilitica? In any case it is one of traumatic obliteration. Two months after the accident the heart and thoracic aorta appeared normal, while two years later cardiac dilatation and hypertrophy developed. In this case, where an anatomical diagnosis was possible two days after the accident, a thrombectomy might have been performed; but the indications for this operation, which would be useless if the thrombus were organised, must be very exceptional.

A NOTE ON THE ASSOCIATION OF CANCER WITH TUBERCULOSIS.

BY CHARLES POWELL WHITE, M.D. CAMB.,
F.R.C.S. ENG.

(From the Christie Hospital, Manchester, and the Helen Swindells Laboratory, University of Manchester.)

In 180 consecutive autopsies on cancer patients at the Christie Hospital I have found 22 cases (over 12 per cent.) in which there was coincident tuberculosis. In this number are included only those in which the tuberculosis was recent and active, evidences of old tuberculosis, such as calcified nodules or fibroid lungs, being disregarded. The diagnosis of tuberculosis was in all cases based on the presence of active giant cell systems with or without caseation. Tubercle bacilli were found in the majority of cases, but in some they could not be demonstrated. A list of the cases is given in the accompanying table.

Table showing Cases of Cancer with Coincident Tuberculosis.

Case	Type of cancer.	Primary site of cancer.	Secondaries.	Tuberculosis.
1	Sq. carc.	Neck.	—	Lupus.
2	Sq. and col. carc.	Rectum.	Liver.	Rectum, glands.

[Notes.—Case 2: Combined lesion in rectum. Case 3: Combined lesion. Case 4: Combined lesion in uterus. Case 5: Also hydatid cyst liver and elephantiasis. Case 16: One gland carcinoma and tuberculosis. Case 18: Also adenoma of liver. The glands referred to are in each case the regional lymph glands corresponding to the primary cancer.

Case 1 was a carcinoma arising in a patch of lupus, but in none of the other cases was the presence of tuberculosis suspected during life. In a few it was detected at the autopsy, but in most cases it was determined only on microscopical examination.

In Cases 2 and 3 the tuberculosis was present in the primary cancer forming a combined lesion. In Case 2 the site was high up in the rectum, and the carcinoma was columnar and mucoid with areas of the squamous type.

In Case 3 the tuberculosis was in an extensive carcinoma of the larynx.

In Case 4 there was a combined lesion of tuberculosis and columnar carcinoma in the uterus. In this case there was also carcinoma of the stomach and ovary, and it is not certain whether the uterine cancer was a metastasis or an independent primary growth.

Case 5 may perhaps be considered as doubtful as regards tuberculosis, since the only evidence of its presence was a psoas abscess. The patient had a large round-celled sarcoma of the testis and a primary carcinoma (squamous) of the peritoneum. He also had a hydatid cyst and cirrhosis of the liver, and elephantiasis of the thigh and scrotum.

In Case 6 there were also two primary tumours, in the mouth and gall-bladder, and tuberculosis of one adrenal.

In Case 7 tuberculosis of the lungs occurred together with carcinoma of the uterus.

In Cases 8–15 the primary cancer was in the mouth, pharynx, or esophagus, and the tuberculosis in the lungs.

In Case 16 the cancer was in the mouth and the tuberculosis in the regional lymph glands and lungs. In this case one of the glands showed overlapping lesions of cancer and tuberculosis, and the cancer was being destroyed by the tuberculosis.

In Cases 17–22 the tuberculosis was found in each case in the regional lymphatic glands corresponding to the primary cancer. Sometimes one gland of a group was tuberculous and the rest cancerous, and sometimes the tuberculous glands were the more numerous, and sometimes all were tuberculous, none being cancerous.

With one or two exceptions, then, the tuberculosis was found either in the primary lesion or in a situation closely connected with the primary cancer—the regional lymphatic glands or, in the cases of cancer of the mouth, &c., the lungs. The tuberculosis was obviously secondary to the cancer in most cases, but whether this was due to the entry of tubercle bacilli through the primary lesion or to the presence of cancer reducing the resistance of the body to bacilli already circulating in the system, could not be determined.

It would be interesting to have the experience of others on this association of cancer and tuberculosis.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF BALNEOLOGY AND CLIMATOLOGY, EPIDEMIOLOGY AND STATE MEDICINE, MEDICINE, AND THERAPEUTICS AND PHARMACOLOGY.

A COMBINED meeting of these Sections was held on March 4th, Dr. W. EDGECOMBE, President of the Section of Balneology and Climatology, being in the chair, when a discussion on the

NATURE, PREVENTION, AND TREATMENT OF FIBROSITIS

was opened by the PRESIDENT. He outlined the present state of our knowledge of the condition, and spoke of the very extensive incidence of "rheumatic" manifestations which constituted one-sixth of the diseases of insured persons and cost £2,000,000 per annum in sick benefit. Until recently the pathogenesis had been exclusively considered to lie in the realm of metabolism; latterly there had been a strong emphasis, perhaps an over-emphasis, on the infective factor. The sources of infection were the mouth, nose, bowel, bladder and kidneys, gall-bladder, uterus and appendages, and vermiform appendix. An encapsuled focus was more likely to set up fibrositis than one with free drainage. Was the pain due to the presence of bacteria in the capillaries and tissue spaces or to circulating toxins? There was no one specific organism; saprophytic bacteria might cause fibrositis when the resistance of the individual was lowered, but the commonest micro-organism found was the *Streptococcus viridans*. The question remained to what extent the onset was determined by the nature of the soil—was the soil rendered fertile by some underlying metabolic disturbance, or could this alone give rise to fibrositis without any infection? Occasionally cases would fail to improve until the soil was altered. Metabolic disturbances to be considered were of three kinds, the gouty, the dietetic, especially those of excessive carbohydrate intake with lack of exercise, and hyperglycemia, both glycosuric and diabetic. The immediate causes included damp, chills, cold, extremes of temperature, sedentary life, overfeeding, and over-exertion. He suggested that the discussion should centre around five questions—namely: (1) Is there a metabolic form of the condition? (2) What are the common sites of infection and the common bacteria? Is there any evidence for the existence of a specific organism or selective affinity between different organisms and types of tissue? (3) What is the value of vaccine treatment, either alone or combined with other methods? (In his experience this had been disappointing in most cases, though striking in a few.) (4) What measures could be adopted to reduce the incidence of the disease among the industrial population? In his opinion these should include improvement of housing conditions, abolition of damp cellar-dwellings, and increase of ventilation and sunlight; improvement of labour conditions, prevention of chills, provision of works-baths and drying-rooms, and the prevention of sepsis in the body from such sources as teeth and tonsils. Individual treatment should be directed both towards the metabolic derangement and the predisposing cause, as well as the detection and removal of septic foci. Local treatment must be varied with the case. He regarded spa treatment as helpful in its promotion of elimination and improvement of bodily nutrition via the circulation and the regulation of the diet. He suggested that the Ministry of Health should consider the extension of such treatment for insured persons.

Statistical Importance of Fibrositis.

Dr. J. A. GLOVER referred to the investigations compiled in 1922 by 49 doctors observing some

92,000 insured persons. Fibrositis alone was costing from £500,000 to £600,000 per annum. Of the 58,000 males 1100 suffered from lumbago, muscular rheumatism, sciatica, or brachial neuralgia. The incidence increased in geometric proportion according to the decade of life. Females suffered far more than males from muscular rheumatism, but the reverse was the case with sciatica and lumbago. The condition was particularly common in South Lancashire, being one of the indications of the premature senility revealed during the compilation of recruiting statistics in the north-west. Metal workers were especially liable on account of the heavy labour and exposure to chills. As the pain of fibrositis was evoked by movement, the factor of strain was likely to play a large part in aetiology. Dental sepsis, particularly apical, seemed to be especially associated with lumbago. Tonsillar infection was not of so much importance as in the case of acute or subacute rheumatism; 13 per cent. of cases of lead poisoning showed signs of fibrositis. Prevention lay along the lines of school inspection and housing. Dental hygiene should be preached to all, as much to the payer of supertax, with his gold crowns over dead roots, as to the poor. The immediate application of first-aid disinfection to cases of minor sepsis and the avoidance of chills in labour conditions would also help considerably.

Sir WILLIAM WILLCOX believed that in those cases where a focus of infection was not found it was because the search had not been sufficiently exhaustive, and pointed out that antrum infection and diverticulitis were two kinds sometimes overlooked. Focal infections were followed by secondary involvement of lymphoid tissues. He believed that the actual lesions were sterile because caused by the toxin, just as colloidal silica could produce fibrositic formations in the absence of any bacteria. Fibrositis was a gauge measuring the balance between virulence and resistance; both seed and soil must be considered. Factors not sufficiently realised to-day were: (1) Sensitisation, which accounted for the occasional failure of vaccine treatment; and (2) symbiosis. Certain diseases lowered the resistance of the individual to the organism of fibrositis—e.g., malaria. Fibrositis was mostly the evidence of a streptococcal septicaemia, of which other general manifestations could be found, such as anaemia, debility, dilatation of the heart, and a history of appendicitis, colitis, &c. Periodical medical inspection by persons skilled in detecting foci of sepsis was the best prevention. Skilled massage was the most valuable local measure, flushing the part with fresh lymph-bearing antibodies.

Dr. P. HAMILL urged the primary importance of establishing the diagnosis, so that cases of diabetes, for instance, should not be treated as fibrositis. He regarded the vast proportion of the cases as infective. The virulence of the infection was low but its chronicity great. In many cases there might be no symptoms, but a tonsil on being pulled forward would exude a milky fluid, although neither enlarged nor painful. Chronic pelvic inflammation in women was less often associated with fibrositis than might be expected. The rectum should be investigated for a hidden fistula. In many cases the infection was generalised and the whole subject must be treated. Removal of the focus was not enough; the residual infection had still to be combated. He had had satisfactory results with saline laxatives, but his success with the usual intestinal disinfectants had not been so great. The resistance must be raised by all hygienic measures, and spa treatment often helped patients whose recovery began to flag after awhile at home. Protein shock led to benefit, which was not lasting; it was suitable for early cases. Vaccine treatment was beneficial if judiciously carried out, at long intervals and in small doses. In the few cases where no focus was found a stock vaccine might be given in a test dose, and the cutaneous reactions should be tested. In the acute stages rest, with splints and extension if contractures were present; in the chronic stages massage and gentle movements should be applied. Patients were more tolerant to this after

diathermy, which produced relaxation and increased blood-supply. The psychological factor in spa treatment was one of great importance, the supineness of the patient being a serious bar to successful treatment.

Dr. R. ACKERLEY believed that any toxin, if retained in the body, was sufficient to cause a painless fibrosis, which became a painful fibrositis when the factor of stress was added. There was no specific organism. Few women over 40 were without fibrotic nodules, but these were painless because there were no circulating toxins, metabolic or bacterial. Metabolic toxins accumulated with age owing to defective elimination by lung, kidney, and skin, and the body stored them in tissues of the least vitality—i.e., fibrous tissue. They failed to be eliminated owing to defective oxidation associated with the imperfectly oxygenated conditions of modern life. This accounted for the increased severity of the pains in bad weather. The cause was rarely simple and all possible factors must be seen to. The failure of dental treatment was due to its incompleteness; every source of sepsis must be removed, and this must be followed up by every possible measure for the restoration of function.

Dr. W. J. MIDELTON deprecated the number of labels used in this connexion; the only one that seemed to be needed was "acute or chronic toxæmia." He believed that streptococci and staphylococci were always secondary to some specific infection such as typhoid or scarlet fever. He had had much success with P. W. Latham's method of continuous counter-irritation, with croton oil and cantharides.

Dr. A. ELMS expressed his belief in the metabolic type of fibrositis; some patients were no better for the removal of their septic foci and vaccine treatment; nor would the septic theory account for the different incidence in the two sexes. He regarded fibrositis as a biochemical condition activated by many causes, of which bacterial invasion was one and one only; two main groups could be distinguished, associated with errors of assimilation and elimination respectively. In the former group the patient was suffering from insufficient food and must be fed up; here there were more women than men. In the second group, the lumbagos and sciaticas, the basis was essentially an eliminative error, perhaps the result of living too well. With increasing age elimination became more and more deficient, hence the proportionate increase of these conditions. Bacterial invasion was not concerned at all in this group; the causal factor was overwork or overfeeding. The work of the late Prof. J. I. Hunter had shown that there were two types of muscle fibre, one concerned with movement and the other with maintenance of posture; it was the latter, innervated by the sympathetic, which was painful in these diseases; pain was not experienced until the movement was completed. There was invariably an increase in the magnesium output in the urine, the calcium remaining unaltered, showing the disturbance in the balance of metabolism. The assimilation-error cases must be treated with acid, acid phosphoric being the best; the result was early cessation of pain, especially at night, and alteration in the magnesium ratio. The second group must be treated with alkali, tribasic potash being the most successful, though it made members of the first group very ill. They must also be flushed out with water to assist the elimination.

Mr. J. McDONAGH pointed out that the condition was one of general involvement of the supporting tissues of the body; seldom was the fibrous tissue alone picked out. The most valuable therapeutic agent was sulphur. He referred to the associated conditions of induratio penis plastica, Dupuytren's contracture, and dermatomyositis. It was in cases of fibrositis occurring in women between 20 and 40 that focal infection played its chief rôle. Gonococcal fibrositis was often not ascribed to its true cause, owing to the difficulty of finding the coccus and its power of lying dormant for many years. In 90 per cent. of cases it was a local recurrence. Acute cases of this type were best treated by the symmetrical urea of meta-benzoyl-meta-amino-benzoyl-1-amino-8-naphthol-3-6-sodium sulphonate (or sum. 36 for

short); chronic cases by intramuscular injections of carbon bisulphide products of diethylamine or contramine. At the female climacteric a distinctive form was met, accompanied by arthritis in the knees and phalangeal joints of the fingers; this was metabolic in origin, corresponding with gout in the male, had a good prognosis and responded well to injections of thiol-histamine. The fibrositis of older people was never seen alone, being one of the clinical manifestations of a general fibrosis; the cause was not ascertainable, and the treatment rested between injections of contramine, insulin, and milk.

Dr. OLIVER HEATH described two personal experiences of lumbago, one following a gumboil, the other an injection of typhoid bacilli. The onset and course argued in favour of a bacteriological causation.

Dr. C. E. SUNDELL was of the opinion that the soil was of greater importance than the seed. The temperature on the whole was subnormal, the skin inactive, and the sweat, when induced, was strongly acid with lactic acid. Treatment should be directed towards flushing out the backwaters of the circulation where fibrositis was liable to occur; exposure to warm moist air for half an hour produced abundant sweating and the excretion of large quantities of acid. Relief was produced, but cure could not be pronounced until the sweat had been rendered neutral.

Dr. M. B. RAY said that during the war "fibrositis" had much the same connotation as "I.C.T.," "P.U.O.," and "N.Y.D." He described the chemical processes occurring in a contracting muscle when there was perfect harmony between nerve stimulation and muscular response. Fibrositis occurred when there was some clogging in the minute lymphatics of the fibrous connective tissue, the treatment was to stop this lymph stasis, and give the digestive system a chance to return to normal.

Dr. HIGGINS referred to the work of continental investigators, and remarked that their results were statistically as good as ours, although they paid little or no attention to focal sepsis. Among their methods were the surgical removal of perithec fat compressing the lumbar cord and the restoration of the lymphatic circulation, particularly in the region of the sacrosciatic foramen, by massage and calisthenics.

Dr. PARKES WEBER expressed his agreement with the observations of Sir William Willcox and Dr. Ellis, in which he saw no essential contradiction.

MEDICAL SOCIETY OF LONDON.

A MEETING of this Society was held on March 9th, Dr. EUSTACE M. CALLENDER, the President, being in the chair.

THE FUNDUS OCULI IN GENERAL MEDICINE.

Mr. ERNEST CLARKE opened a discussion on this subject. He said that ever since the ophthalmoscope was invented medical men had increasingly realised its help in diagnosis and treatment; and its use in medicine had been enormously advanced since the introduction of the luminous ophthalmoscope, which had brought ophthalmoscopy practically within the reach of all. As this instrument could be brought so near to the eye that it almost touched the cornea, it was not necessary for the examiner to have a darkened room, and the patient could be examined in any posture. In addition the reflection of light from the cornea was much lessened, enabling the observer, sometimes, to see through a pin-point pupil, and even inspect the macula. The normal fundus showed a great number of variations, hence it was only by much practice and by looking at every available fundus that the observer acquired the capacity of recognising an appearance which was abnormal. Otherwise he would become alarmed needlessly when he saw such gross changes as opaque nerve-fibres or colobomata, which were of no clinical significance, while he might miss the important fine changes which ushered in the onset of arteriosclerosis.

Picture Records of the Fundus.

Mr. Clarke said an important further advance in the subject had recently been made. At the suggestion of Dr. Rayner Batten, Messrs. Hamblin had recently opened a studio, staffed by trained artists, for making accurate colour-drawings of ocular fundi. The aim was to avoid wearying the patient and keeping the eyes lighted up too long, and therefore the artists had been trained to memorise what was rapidly seen until it had been drawn. At a few minutes notice a patient could be given an appointment and the picture taken while the eye was still under a mydriatic. A great advantage of this was that repeated pictures could be taken, so that a record of progress could be kept in a successful case; or if it were not favourable, the record showed in what direction the disease was advancing. Colour drawings possessed a great advantage over black-and-white ones.

Mr. Clarke showed a number of instructive pictures which had been made in the way described, and gave the histories of the conditions they illustrated. One was that of a woman, aged 42, who was being treated for rheumatism and pyorrhoea. Vision was hyper-normal, 6/5 in each eye. Papillitis and hæmorrhages were present in both eyes. There was swelling of the disc in the right eye to +2, and of that of the left +3. Her teeth were attended to, she was auto-inoculated, she gradually improved, and the manner in which the eyes indicated the progress was plainly shown by the pictures of the fundus. In contrast to this was the case of a man, aged 48, who had 6/9 vision in each eye, but it was recently becoming worse. He was suffering from pyorrhoea and intestinal toxæmia. Papillitis was present in both eyes, and a serious view of the case was taken. A few weeks later there were choked discs, but the man had no headache or sickness, though the fundus appearances pointed to brain tumour. After consultation with a physician, a decompression was decided upon, but the patient died on the table. Post mortem, a fairly large glioma was found on the right side at the junction of the occipital and temporal lobes. One of the large series of pictures he showed had reference to a case of veronal poisoning. A woman, aged 61, was much worried and suffered from insomnia. To secure sleep she took a very large dose of veronal. When the speaker saw her she had marked papillitis and retinitis, with hæmorrhages in both eyes, particularly the left. The appearances were such as to suggest cerebral tumour, but under treatment she gradually improved, and a month later the papillitis and hæmorrhages had disappeared, leaving only a slight post-neuritic blurring of the disc, and this subsequently ceased leaving both fundi normal. Another series showed gradual improvement of diabetic retinitis under insulin treatment.

In conclusion, Mr. Clarke said it would be generally agreed that a collection of fundus pictures, accurately drawn—many pictures referring to the same case—formed into a permanent library, would be of enormous use. Copies of these pictures and lantern slides of them could be obtained with the consent of the doctor, and they would be a great aid in educational work. As the names would never appear, the patient's consent was not necessary.

Discussion.

Dr. JAMES COLLIER said an ophthalmoscopic examination should be made in every case of illness, whatever its nature. It could be done very quickly and afforded valuable information. To the beginner every fundus was of interest, and he should practise on normal people, to enable him readily to detect the abnormal. In his own wards every student was obliged to use the ophthalmoscope on every patient, and he criticised what the students reported they saw. In this country much more attention seemed to be paid to ophthalmoscopic examinations than in America. In many diseases the first symptom might be ocular. Even more important than positive findings in general medicine were indications that the ocular fundi

were normal. In the presence of such symptoms as headache, giddiness, and transient blindness it was impossible, without an ophthalmoscopic examination, to treat the condition without a lurking suspicion that a serious organic condition underlay the symptoms. On two occasions he had been called to cases having severe symptoms and the patient expired almost immediately; yet the ophthalmoscope revealed intense papillitis and proved the existence of a cerebral tumour. But there had been no complaint of headache. Often examination of the fundus oculi settled the diagnosis in otherwise doubtful cases. In one case a little girl was admitted to hospital with urgent symptoms of meningitis; she was unconscious, and had head retraction and vomiting. Lumbar puncture resulted in a large quantity of blood-stained fluid being withdrawn. Twenty minutes later she was sitting up and playing with toys. After recovering from her unconsciousness she was found to have asteriognosis down the right side, showing the probability of a lesion in the parietal lobe. His diagnosis was that she had had a sub-arachnoid hæmorrhage, which had torn up part of the parietal lobe, probably arising from a congenital aneurysm. An alternative diagnosis of poliomyelitis was offered by a colleague, but in one eye, just round the disc, there were three small groups of fine superficial hæmorrhages, and these had never been reported in association with poliomyelitis, but were a frequent accompaniment of subarachnoid hæmorrhage.

Dr. PARKES WEBER referred to ophthalmoscopic appearance as a clinical sign of recent death. He said his attention was directed to the subject by chance when he was house physician in 1892, by a case in which the heart ceased to beat while he was examining the patient's optic disc with the ophthalmoscope. In the same year he was called to a patient just after death had occurred, and he found the columns of blood in the retinal blood-vessels interrupted by small spaces, looking like the segmentation which sometimes occurred in the mercury column of a manometer. He found that by exerting pressure on the chest these small spaces could be moved backwards and forwards. In one case a single spontaneous inspiration took place after he had found this ophthalmoscopic phenomenon of segmentation was already present. He gave references to observations of a similar nature which had since been made by others, both on the continent and in America. M. H. Kahn, in his most recent paper on the subject, 1924, entitled "A New Vascular Sign of Death," said that *in vitro* segmentary coagulation could be produced, but not without difficulty, and concluded that segmentation in the venules and arterioles was a definite sign of death and that it should rank equally with the other clinical signs of death. Dr. Weber said it should not be inferred, in the absence of this sign, that the person was not yet dead.

Dr. RAYNER D. BATTEN showed a series of consecutive drawings of fundi illustrative of the changes seen in association with various diseases, including the macular changes seen in mental degeneration. A record in words, he said, failed to convey a proper impression of the condition seen, and hence consecutive pictures were the only means to this end. He urged that medical men should be willing to supply a note of the clinical features of cases of which fundus drawings were made.

Fundus Changes in Toxicæmic States.

Sir WILLIAM WILLCOX agreed as to the great importance of ophthalmoscopic examinations in ordinary medical work. In every case the fundus ought to be examined, and if that were done more would be known about the relationship of the eye changes to general diseases, and diagnoses would be more accurate. He said he had recently been interested in the changes in the fundus oculi in association with toxicæmic cases. Until comparatively recently it was taught that fundus changes were either due to diabetes, or to Bright's disease, or to high blood

pressure. But it was quite common to find hæmorrhages and other changes in the fundus in cases showing no increased blood pressure and whose renal function was normal. In such cases it was most important to search for every avenue and channel of infection. When such were found and put right, it was surprising how soon the fundus changes cleared up. He usually included among the measures in such cases Plombières treatment, as there was often a secondary septic involvement of the colon. Some drugs seemed to show a special affinity for retinal tissue, and a good example of that was atoxyl; in certain people quinine had a similar special effect, and he related a case in which a large dose of quinine given mistakenly for malaria produced temporary blindness. With regard to veronal poisoning, he said a number of nervous symptoms were recurring to-day—usually attributed to other causes—which seemed to be a sequel of medicinal treatment by veronal at some previous date. He asked why certain patients with a focal infection had retinitis. Was it because retinal tissue was specially sensitive to the toxin? Or were the patients sensitised to the toxin, which was usually a streptococcal one? When retinal changes were present he thought special care should be exercised in the use of vaccines, and said that his own practice was to start with only 5000 or 10,000, instead of the usual millions because of this sensitisation, which was akin to asthma and angioneurotic oedema.

The PRESIDENT spoke of the value which a book consisting of a collection of pictures of fundus appearances associated with various diseases would be to the general practitioner, who had sufficient experience to recognise from what he saw that something was wrong, but often he was not familiar enough with the changes to base his diagnosis upon them.

Mr. CLARKE briefly replied.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on March 5th, Dr. E. F. MAYNARD, the President, being in the chair.

Mr. H. N. FLETCHER read a paper on some points in connexion with the

Painful Dyspepsias and their Diagnosis.

After remarking that the old view of hyper-acidity as the cause of pain had been discarded, except in so far as it might be so indirectly, he described the experiments of Hardt, Carlson and others, and their evidence that increased intragastric tension was the true cause. The recent views of A. F. Hurst as to how this increased tension was brought about by the reflex influence of diseased states within and without the stomach were referred to, and the need for further knowledge of the neuro-muscular apparatus of the stomach, the exact part played by the vagus and sympathetic nerves, and their possible control through Keith's nodes was emphasised. Mr. Fletcher then described in detail the salient characteristics of the common causes of painful dyspepsias, gastric and duodenal ulcer, gastric cancer, cholecystitis, chronic appendicitis, visceroptosis and "nervous" dyspepsia, and laid stress upon the paramount necessity of a detailed history and physical examination of the patient—the important differential points of which, in making a diagnosis, he described.

Discussion.

The PRESIDENT in his remarks agreed with Mr. Fletcher in his statement regarding the time incidence of pain, as a differentiation between gastric and duodenal ulcer. As regards vomiting, this is not at all characteristic of gastric ulcer. If, for instance, epigastric pains and vomiting are present one would think at once not of gastric ulcer but gall-bladder or duct. The pain in the gall-bladder radiates up to the right shoulder. We must not, he said, lose sight of the fact

that epigastric pain may be due to angina, pericarditis, or pleurisy. He considered that in neurasthenics there were almost as many cases of hypochlorhydria as hyperchlorhydria.

Mr. G. W. BERTSFORD considered that in neurasthenic subjects slight pain is exaggerated into severe pain. Excluding nervous dyspepsia, epigastric pain, he said, is due to organic lesion in the upper abdomen.

Dr. W. BROADBENT said that in his experience of duodenal ulcer there was seldom any previous history of dyspepsia. He referred to the diminution in the number of gastric ulcers of recent years and suggested that modern hygiene might account for this. Neurasthenic dyspeptics complain of very severe pain but absence of tenderness on palpation.

Dr. DONALD HALL drew attention to the great care Mr. Fletcher took in studying the clinical history and symptoms of his patients. He would like to support the statement Mr. Fletcher had made that X rays were not so reliable in duodenal as in gastric ulcer, and he quoted three cases. A medical man, aged 47, had symptoms of duodenal ulcer for seven years with typical time incidence, relief from the taking of food and alkalis, and with the characteristic remissions. By X rays a diagnosis was made of chronic duodenal ulcer, but the surgeon whom he consulted advised a course of strict Sippy diet for six months. On this régime the patient was free from symptoms, but before the six months had elapsed he had for the first time pain and tenderness in the right iliac fossa. He was operated on the same evening when the greater part of the appendix was found to be represented by a mere cord, while the proximal stump was acutely inflamed and would have gone on to perforation. That patient had had repeated mild attacks of obliterative inflammation without at any time pain or other symptoms in the region of the appendix, but in his case there was a possible fallacy because the surgeon did not feel justified at the laparotomy in exploring the upper abdomen, and there may have been a coexisting duodenal ulcer. He had, however, on ordinary diet, now been free from symptoms for 18 months. A middle-aged clergyman had suffered from painful dyspepsia for several years and had declined exploratory laparotomy. He had written to Dr. Hall stating that at last it was known what had been at fault; he had been X rayed and was found to have dropped colon for which he asked Dr. Hall to treat him. While reading the letter an urgent message came to see the patient. Dr. Hall found him in acute agony as from perforation. He was operated on that morning and a large tear found in a chronic ulcer of the duodenum. He died the following day. A retired lieutenant-colonel, aged 56, with a long history of dyspeptic troubles was X rayed in London. Lane's kink and visceroptosis were found, and after elaborate surgical operation he was sent down to Brighton to convalesce. Taken ill during lunch he was seen in the lift at his hotel and at first sight appeared to be dead. When later on it was possible to move him to his bedroom he was found to have fainted as a result of severe internal hæmorrhage. Melæna was present for days, and after medical treatment for several weeks gastro-enterostomy was performed and the clinical diagnosis of duodenal ulcer was confirmed. Dr. Hall stated that he was a firm believer in "appendix dyspepsia" as a clinical entity, but where local signs were wanting the mentality of the patient must be carefully studied before operation. Abdominal operations based solely upon subjective symptoms were to be deprecated.

Dr. W. BARRINGTON PROWSE said that too much must not be expected from X ray examinations and the result must always be taken in conjunction with the clinical evidence, but there is no doubt that X ray examinations are a very valuable help in doubtful cases. He considered that in supposed gastric cancer X ray is extremely valuable as a help in determining the question of operation.

Dr. H. M. GALT showed microscopical slides of sections of stomach through one of the rugæ; stomach with the vessels injected; small intestine and small intestine with the vessels doubly injected.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on March 5th, with Dr. PETER HOWIE, the President, in the chair.

Exhibition of Cases.

Dr. WILLIAM BROWN showed a case of *Hirschsprung's Disease* in a boy of 3 years, the youngest of a family of eight. There was no history of tubercle or syphilis in the family, and the patient's Wassermann reaction was negative. There was a history of attacks of diarrhoea during the past 18 months with swelling of the abdomen, visible peristalsis, and rumbling noises, which all disappeared temporarily when an aperient was given. There was no constipation. On admission to hospital there was visible peristalsis of the large bowel. Screen examination after a barium enema showed an enormous pelvic colon lying in the right iliac fossa and extending up to the liver with dilatation of the descending and transverse colon. Treatment consisted of lavage with saline solution, at first once, later twice, daily, with a weekly dose of castor oil; great improvement followed—peristalsis ceased, the abdomen decreased in size, and the tone of the wall improved. A recent barium enema showed a smaller calibre of the colon and better tone of its walls. The patient was not confined to bed. Photographs and tracings of the radiographic examinations were shown.

Mr. ALEXANDER MITCHELL showed a boy in which treatment of a *Streptococcal Arthritis of the knee* by Willems's method had resulted in a completely mobile joint. He emphasised the necessity of making the incisions the whole length of the joint, and of full active movement. Pain was an obstacle to movement, but by adopting Everidge's method of a back splint slung by an arrangement of weights and pulleys the effect of gravity could be almost entirely eliminated.

Dr. A. G. ANDERSON showed a boy who had sustained a *Fracture of the Skull* in a motor accident, where the signs and symptoms showed the presence of a right-sided cortical lesion. Immediate operation revealed a diffuse meningeal hæmorrhage, and decompression was followed by recovery, practically complete in two days. There were no sequelæ.

Mr. WILLIAM ANDERSON presented a tailor, aged 31, who complained of loss of power in extending the fingers of the right hand. It was found that the extensors communis digitorum and carpi ulnaris did not react to faradism. There were no sensory changes. X ray showed uniform thickening of the shaft of the radius, and the Wassermann reaction was strongly positive. All ordinary treatment by electro- and physio-therapy had proved useless.

Mr. G. H. COLT demonstrated a small loose bone removed from the upper end of the olecranon fossa in the elbow-joint, and showed radiograms. It was of interest to speculate as to the origin of the loose body—was it a chip off the epiphysis which had gone on growing, nourished by the synovial fluid, or did it represent an actual complete ossific centre?

STATE DISTRICT MEDICAL ASSOCIATION, U.S.A.—H.R.H. the Duke of York has signified his willingness to accept the honorary membership of the Inter-State Post-Graduate Assembly directed by the State District Medical Association. This will be conferred upon him at the inaugural ceremony on June 2nd at the Royal Society of Medicine, when the visit of the Association to this country commences. The following also will be made Honorary Members: Mr. Austen Chamberlain, Mr. Neville Chamberlain, Lord Desborough, Lord Dawson of Penn, Sir Humphry Rolleston, Sir John Bland-Sutton, Sir St. Clair Thomson, Sir Holburt J. Waring, Mr. Philip Franklin, and Sir John Y. W. MacAlister.

Reviews and Notices of Books.

PSYCHO-ANALYSIS.

Collected Papers. Vols. I. and II. By SIGM. FREUD, M.D., LL.D. Authorised translation under the supervision of JOAN RIVIERE. London: Hogarth Press. 1924. Pp. 359 and 404. 21s. each vol.

It is 32 years since Freud and Breuer published a joint article which became the starting-point of psycho-analytical practice and theory, and these volumes, the first instalment of a projected series of four, carry on the story of the growth of psycho-analysis from that beginning. Study of the development of a theory is not perhaps necessary to a practical understanding of it, but the order of development of this theory indicates the path that an investigator might follow who set out to test it by clinical experiment. The opening paper critically appraises the value of Charcot's work, and in the second, the joint article referred to above, the authors claim to have made a further step along the path which Charcot first opened up and describe the curative effect of the abreaction of accumulated stimuli arising from memories which are "not at the disposal of the patient in the way that his more commonplace memories are." This was the germ of Freud's theory of the unconscious, but the method was not yet that of psycho-analysis; it was that of the revival of memories in a hypnoidal state, which was freely used in the treatment of "shell-shock" during and after the late war. In the fourth paper, dated 1894, Freud describes the *defence neuro-psychoses* in which the affect—i.e., the emotional charge—of an unbearable idea becomes the source of symptoms, and he declared that the unbearable idea is always found associated with the sexual life. In separating the *anxiety neurosis* from "neurasthenia" he states as a principle of clinical medicine that the psyche "develops the neurosis of anxiety when it feels itself unequal to the task of mastering (sexual) excitation arising endogenously." Here Freud entered upon that period when, as he expresses it in another chapter, he settled down, like Robinson Crusoe, as comfortably as possible on his island. This isolation lasted ten years though, as he points out, he had advanced nothing new by suggesting the sexual aetiology of the neuroses, for undercurrents in medical literature acknowledging these facts had never been absent, though the official medicine of the schools has behaved as if it knew nothing about it.

A reply to Lowenfeld's criticism of the theory of this "actual" neurosis suggested that such factors as hard work, worry, or definite shock are operative only when sexual difficulties are present, but it is to be noted that in his "Introductory Lectures," written at a later date, Freud states that the "traumatic neuroses" cannot be correlated with his general scheme. He has also retraced his steps in regard to the influence of sexual trauma in the aetiology of hysteria, and describes his bewilderment (p. 299) when he found to be untrue some of the statements of hysterical patients concerning sexual experiences in early childhood. This led to the realisation that since these patients traced their symptoms to fictitious traumas, thus creating such scenes in phantasy, psychological reality must be taken into account as well as actual reality. An important principle is here established—that what the nervous patient believes, whether true or false, must be given validity in any scheme of psycho-pathology and itself be made the subject of analysis.

The final chapter of the first volume gives a history of the psycho-analytical movement with the controversies that led to the secession of Jung and Adler. The former has, according to Freud, bowed to the storm and abandoned the psycho-analytical position in an effort to placate opposition by eliminating the disagreeable, whilst Adler's secession is traced to

personal ambition. Freud himself certainly never trims his sails. The chapter, in the second volume, on sexual morality and nervousness will, perhaps, frighten the cautious with its observations that the double code of morality conceded to the male in our society is the plainest admission that society itself does not believe in the possibility of adherence to those precepts which it has enjoined on its members, whilst under the disappointments of matrimony women succumb to severe lifelong neurosis. But it should be studied in relation to the chapter on the future of psycho-analytic therapy, where are sketched the possible results of the general diffusion and acceptance of psycho-analytic doctrine. The countless numbers who take flight into neurosis "would have to be honest, own up to the instincts that are at work in them, face the conflict, fight for what they want or go without, and the tolerance from the community which is bound to ensue as a result of psycho-analytical knowledge would help them in their task." Alarming this may be, but it does not of necessity involve moral disaster to our civilisation. In an equally outspoken chapter on the transference-love Freud emphasises those obligations, the general observation of which has always permitted the confidential relation between physician and patient.

Freud wrote, in 1914 (Vol. I., p. 328), that he was either compared with Darwin and Kepler or was hooted at as a general paralytic. The gradual spread of his theories in the face of strenuous opposition points to a vitality that distinguishes them from a passing craze, and the possibility is emerging that his place may indeed be among the pioneers. These volumes may, then, be studied as a record of history in the making.

ACUTE INFECTIOUS DISEASES.

A Handbook for Practitioners and Students. By J. D. ROLLESTON, M.A., M.D. Oxf., Senior Assistant Medical Officer, Grove Fever Hospital, London. London: William Heinemann. 1925. Pp. 376. 12s. 6d.

MANY workers in fever hospitals must have cherished the hope that Dr. Rolleston would one day embody his exceptional experience of the infectious diseases and the literature concerning them in a manual such as this.

The handy volume before us contains an astonishing amount of information in its 376 pages. Much space has been saved by the complete omission of illustrations and temperature charts, the author holding that the bedside is the only place for the study of cutaneous lesions and the course of pyrexia. Admitting that many pictures are useless or even misleading, some may be really instructive, for instance, well-chosen photographs illustrating the differential diagnosis of small-pox and chicken-pox. As regards temperature charts, we believe that their omission is a mistake, especially in a book intended partly for students. In his description of the various fevers, moreover, the author does not always give a very clear idea of the course of the temperature, as, for example, in his chapters on scarlet fever and measles. The prodromal temperature of the latter especially is not described in such a way as to make a student realise the importance of the remission, which so often leads the medical attendant to the premature conclusion that the case is not going to be one of measles after all. In the same way no description can be quite as effective as the chart of an actual case showing the primary and secondary fevers of small-pox. For the practitioner with some knowledge of the subject, however, this defect, if it be one, is of little moment, and in any case it may be doubted whether the book is quite suitable for the student. It contains much more than is required for examination purposes, and, in particular, goes so fully into quite exceptional complications as to leave an exaggerated impression of their importance, though we must do Dr. Rolleston the justice of acknowledging

that he lays emphasis on their rarity. It is to those whose work lies in fever hospitals that the volume will be most valuable. It gives a quite admirable survey of the whole literature, and a very full bibliography is appended to each chapter. Even the most industrious readers will find much in it that is new to them and will be stimulated to be on the look-out for some of the more unusual complications of the various diseases.

A word of special praise is due to the brief historical notes with which each chapter opens, and which give just the information required. A little more space might have been given to the sections on differential diagnosis. Admitting the rarity of typhus in this country, its distinction from enteric fever deserves more space than that allotted to it, and the diagnosis of rubella from scarlet fever and measles is also treated somewhat scantily. A more serious defect is the total omission of the differentiation of chicken-pox from small-pox, the reader being referred from each chapter to the other only to find cross-references. It is curious that in a book so well up to date—an excellent account of the very recent work of Dr. and Mrs. Dick on scarlet fever is given—Dr. Rolleston has endorsed what we can only regard as the original error of Schulz and Charlton in their interpretation of their "extinction" test. As W. Mair pointed out a year ago, and as is now generally held, the blanching of a scarlet fever rash is not caused by a normal serum, but by the serum of either a convalescent from scarlet fever or of someone who has acquired an immunity to that disease either by having had an attack of it or in some other manner.

We have enjoyed those chapters in which the author has allowed his own experience and opinions to appear clearly; that on diphtheria is a good example. Other chapters of special interest are those on Vincent's angina, the paratyphoid fevers, and erythema infectiosum. Throughout the volume the statistical figures taken from the records of the Metropolitan Asylums Board will be found useful for reference and comparison by those in charge of hospitals. Dr. Rolleston's book will, we are assured, be of great use to many practitioners as well as to workers on fever.

PERNICIOUS ANEMIA AND APLASTIC ANEMIA.

A Contribution to the Study of Pernicious Anemia and Aplastic Anemia. By ARTHUR SHEARER, M.D. Bristol: John Wright and Sons, Ltd. 1924. Pp. 94. 7s.

IN this volume, a thesis presented for the degree of Doctor of Medicine in the University of Leeds, the author gives a clear and comprehensive account of all that is known and of much that is merely suggested in regard to pernicious anemia. Section I., which deals with this condition, is a model of what an essay on a medical subject should be and amply justifies the award of the degree "with distinction" which his thesis achieved for its author. Section II. deals with the aplastic anemias. Little new light is thrown upon this complex problem, but Dr. Shearer does good service merely in coming into the open with an expression of views upon a subject concerning which there is a very considerable amount of haziness in the minds of many medical men—laboratory workers and clinicians alike.

ELECTRICITY IN DIAGNOSIS AND THERAPEUTICS.

Leitfaden der Elektrodiagnostik und Elektrotherapie. Seventh edition. By Prof. Dr. TOBY COHN, Nervenarzt in Berlin. Berlin: S. Karger. 1924. Pp. 232. G.m.7.20.

THE seventh edition of this book, like those which have preceded it, deals at length with the subject of electro-diagnosis. Electrotherapy is considered in the second half of the volume. The first 107 pages are devoted to the study of the electrical reactions of muscle and nerve. After a brief description of apparatus, the author has written an account of that

part of the physiology of muscle and nerve which is relevant to the subject of reaction-testing. The reactions in health and disease and the methods of testing them by the faradic and galvanic currents are described in detail, and the meaning and clinical significance of the different reactions are discussed. In the present edition the author has added a note on the chronaxie and the work of L. Lapicque and L. Bourguignon. He refers to the lengthening or shortening of the chronaxie in various diseases, but does not discuss the possibility of gaining additional information of clinical value by means of the chronaximeter. In the second part of the book the therapeutic properties of the various electric currents are considered and instructions are given for the treatment of various diseases and morbid conditions by these currents. The faradic and galvanic currents are most fully considered. Short chapters on treatment by static electricity, sinusoidal currents, and condenser discharges are added. The chapter on high-frequency currents and diathermy is too brief in relation to the importance of these subjects.

This book is of value mainly for the complete accounts which it contains of the uses of the faradic and galvanic currents for diagnosis and treatment. The plates showing the positions of the motor points are among the clearest and most instructive that have been published. The superficial muscles are shown together with the nerve trunks where the latter are closest to the surface. Over each plate is placed a sheet of tissue paper. This partly obscures the drawings of the muscles, but shows the position of the motor points where the testing electrode should be placed. The tissue paper can be raised when desired, so that the operator can obtain a guide to the relationship of the muscles which he is testing.

REJUVENATION BY GRAFTING.

By Dr. SERGE VORONOFF. Translated by FRED. F. IMIANITOFF, B.A. Lond. London: George Allen and Unwin, Ltd. 1925. Pp. 224. 15s.

Dr. Voronoff's work is already well known in this country, although this is the first time that an official translation has appeared. The preliminary chapters are historical and deal with early experiments in grafting senile rams. A point of great interest, however, is the fact that according to the author a testicle taken from a six months ram and implanted into the scrotum of a senile ram continued progressively to develop, and to pass from the prepuberal stage to that of spermatogenesis. This, of course, means that not only did the graft preserve its vitality, but that it definitely completed its progressive development in its new surroundings, a claim that is considerably in advance of that made by other workers in the field of grafting. Dr. Voronoff then describes how his early successes amongst animals induced him to attempt a similar feat in the case of man, and he narrates how the work of Grunbaum, Bruch, Thorek, and others on the similarity of the serum reactions in man and the anthropoid apes led him to choose a chimpanzee as a source for his grafts. The results he obtained are given in detail in 44 case-sheets. Summarising these one may see that in the great majority of cases benefit to the general health, mental vigour, and muscular activity of the patients grafted appear to have taken place, whether the grafting were done for senility or for testicular insufficiency. In those cases, however, in which the operation was carried out for sexual neurosis and impotence, the results were generally negative. The book concludes with chapters by Dr. Edward Retterer on the structure of the chimpanzee's testicle, and on the histology of testicular hetero- and homo-grafts.

The book is written by an enthusiast and there are statements within its covers which cannot be accepted without reserve. However, it must be admitted that Dr. Voronoff has accumulated a great deal of material in support of his thesis, and for this reason his work merits attention.

A HANDBOOK OF MIDWIFERY.

Sixth edition, enlarged. By COMYNS BERKELEY, M.C., M.D. Cantab., F.R.C.P. Lond., Obstetric and Gynaecological Surgeon to the Middlesex Hospital. London: Cassell and Company, Ltd. 1924. With colour frontispiece and 74 illustrations in the text. Pp. 578. 8s.

A BOOK which has reached a sixth edition requires little testimony as to its usefulness or popularity. This little handbook, written mainly for candidates sitting for the Central Midwives Board examination, contains not only sufficient theory for that purpose, but also much practical information upon the hygiene of pregnancy and lactation. In cases where breast milk is deficient, as shown by test-meals, complementary rather than supplemental feeding is advocated. The section dealing with artificial methods of feeding is particularly good and includes various formulæ for the modification of cows' milk; these appear to be based upon the percentage system of Truby King. This edition has been thoroughly revised and, in places, rewritten.

PHARMACOLOGY AND THERAPEUTICS.

Medicamenta Recentia of Allen and Hanburys. Second edition. 1925.

THOUGH primarily concerned with the products of Messrs. Allen and Hanburys, this neat little book is something much more; it is an index of the drugs applicable to modern methods of treatment and helps to supply the gap, so often felt by the practitioner, between the new methods of treatment invented by scientific pioneers and used by specialists and the same methods as they can be applied in general practice. Apart from the full list of drugs there are short explanatory notes on medical matters which have been prominent in recent years. Chief among these is an excellent summary of the Dangerous Drugs Act, and we recommend that a similar summary on scheduled poisons should be inserted in the next edition. Other subjects annotated are the recent advances in diet, Graham's method, Allen's method, dietetic control and insulin, and the Lenhart diet. Blank pages are included at the end for the medical man's personal notes on his cases, and we may suggest that if these periodical observations were made by any large group of practitioners carefully and with dates, a compilation of them should be of high practical value, especially if any following-up of the cases of interest were pursued.

ORGANIC MEDICAMENTS AND THEIR PREPARATION.

English edition. By ERNEST FOURNEAU, Head of Laboratory for Therapeutic Chemistry in the Pasteur Institute; Member of the Academy of Medicine; formerly Director of the Poulenc Laboratories. Authorised translation by W. A. SILVESTER. With prefaces by EMILE ROUX and GEORGE BARGER. London: J. and A. Churchill. 1925. With 22 illustrations. Pp. 262. 15s.

THIS book consists of a series of lectures on the composition and chemical preparation of a number of substances in use in therapeutics. Dr. Fournéau begins with guaiacol and phenacetin, explaining first the principles and then the detail of their formation from phenol; he then deals in a similar manner with some of the antipyretics, hypnotics, local anaesthetics and antiseptics, organic compounds of arsenic and mercury, and the first part is completed by a consideration of the structure of adrenalin and the phosphatides. The second part consists of practical directions for the preparation in the laboratory of about 30 of the substances discussed. The book ought to have considerable effect in arousing interest among young organic chemists in chemo-therapeutic research; it is both terse and simple, and in it is

revealed the outlook of one who combines a first-rate practical sense with imagination and enthusiasm. There are many suggestions of problems needing attack. Dr. Roux, Director of the Institut Pasteur, who has written a preface to the original French edition, describes the book as being above all a programme, and a call to his countrymen to enter a field of important research which they have largely neglected.

The appearance of the book in English, as well as in French, may have important consequences; it is said, for example, that recent brilliant developments of physiology in America have been in some measure due to the influence of Bayliss's "Principles of General Physiology." Fournéau's book may well have similar effects, and it is to be hoped that teachers of pharmacology and organic chemistry will not fail to introduce the book to their more promising pupils.

BOOKS FOR NURSES.

(1) *Applied Chemistry for Nurses.* With Laboratory Experiments. By JOSEPH L. ROSENHOLTZ, Ph.D., Assistant Professor of Geology in the Reusseler Polytechnic Institute, New York, &c. London and Philadelphia: W. B. Saunders Company. 1924. Pp. 220. 10s. 6d.

(2) *Fundamentals of Chemistry.* A Text-book for Nurses and other Students of Applied Chemistry. By L. JEAN BOGERT, Ph.D., Research Chemist, Obstetrical Department, Henry Ford Hospital, Detroit, &c. W. B. Saunders Company. 1924. Pp. 324. 14s.

Prof. Rosenholtz's book consists of two parts, the first dealing with the theory of chemistry and the second with experiment. The former attempts to give a complete elementary view of chemistry from a medical aspect. The descriptions are not well balanced, swaying between extreme simplicity and complexity. On the one hand we have a warning about not writing the second letters of an element like Sn in capital form, whilst on the other we have a proposed graphic formula for morphine, occupying about half a page. The experiments are in the most case pointless.

The nurses of America must indeed be remarkable, for, according to the author, in a course of 20 hours, for both theory and practice, they are taught the whole of chemistry. The following questions, taken at random from the author's tests at the end of his chapters, are among those which they are apparently supposed to be qualified to answer: Discuss the size of the protein molecule. How are ptomaines formed? Discuss the various steps in the formation of coal. Discuss the use of radium, and What is steel? Compared with this the claims of certain "Language Institutes" to teach one to speak foreign tongues without a master in 24 hours are as naught.

Exactly the same reflection occurs to the mind in reading Dr. Bogert's treatise, which is a far better book. He attempts to give a complete general account of chemistry, organic, inorganic, physical, and physiological, within the space of 324 pages. A preliminary glance at the table of contents would give the impression that he has set himself an impossible task. On reading through the book, however, one is impressed with the extraordinary thoroughness of the descriptions, and when the last page is reached it is realised that the author has achieved his object. The first 15 chapters are devoted to inorganic chemistry, together with a few references to physical chemistry. Chapter XVI. deals with the physiological importance of inorganic salts and their use in the body. The author points out that although inorganic salts have no food value, they are of the greatest importance in maintaining osmotic pressure, constant reaction, and normal growth and development. A series of photographs shows the effect of calcium and iodine starvation upon the growth of cattle. The remaining eight chapters

are devoted to organic and biological chemistry. The concluding chapter deals with urine and faecal analysis. In his introduction, the author states that he intends the book for general students, but particularly for nurses. Although the book itself is excellent, we cannot help but comment upon its value to nurses. Surely there are much more important points for nurses to study than many of the sections contained in this volume. Those engaged in routine hospital work, in this country at least, know that the average nurse requires much training in measurement before she can be trusted to collecting an accurate 24 hours' specimen of urine, and it would seem rather ill-advised to attempt to teach her the ins and outs of the periodic law, or the theory of the action of indicators. A series of questions is appended to each chapter. One wonders what the answer of a qualified English nurse would be to a request to "Enumerate the main assumptions or hypotheses which make up the ionic theory."

Elementary Science for Nurses. By W. F. LLOYD, B.A., M.B. Camb. With a Preface by Sir D'ARCY POWER, K.B.E., F.R.C.S. London: J. and A. Churchill. 1925. Pp. 95. 3s. 6d.

IN this little book the author deals with those aspects of physics and chemistry of interest to nurses. The treatment is adequate and concise. One of the most commendable points is that he gives a detailed account of the metric system. Although elementary, this is very necessary, since the majority of nurses find it difficult to translate minims and inches into metric units. Sir D'Arcy Power adds a charming introduction, in which he outlines the history of the nursing profession. The book should have a wide circulation.

MARTIN ARROWSMITH.

By SINCLAIR LEWIS. London: Jonathan Cape. 1925. Pp. 480. 7s. 6d.

Martin Arrowsmith, student and later doctor of medicine, spends most of the earlier years of an adventurous life restlessly seeking to satisfy the conflicting needs of a mind too responsive to environment. It takes him nearly all the pages of Mr. Sinclair Lewis's great story to learn with pain that even for imperious youth, bred from pioneer stock, it is impossible to serve several gods and retain sanity. The story of his career, of the ideals he follows, examines, and discards, of the master he worships and twice betrays, must stir the memory of every medical man, for none can entirely have escaped such experiences.

Martin Arrowsmith divides his time no more neatly between work, drink, and love, than do certain of the more mediocre students of his year until he is inspired by the personality of Max Gottlieb, professor of bacteriology, with a bewildered enthusiasm for science. Gottlieb is a teacher worthy of adoration, as whose assistant, until other interests are allowed to encroach on his work, Martin tastes the delights of original research. A careless blunder—and perhaps a too severe rebuke—drives him in his touchy pride towards the clinical side of medicine, for which he is temperamentally unfitted. Partly out of pique, mainly to enable him to support as his wife a girl whose habit of giving inarticulate sympathy and demanding almost nothing in return enables her to endure him without unhappiness, he enters general practice, and boasts loudly that nothing could draw him from a life devoted to healing the sick to the dry monotony of a laboratory. Unfortunately, he lacks tact, discretion, and even judgment at crucial moments, as when he travels 50 vain miles to fetch antitoxin instead of doing a tracheotomy. It is obvious even to his arrogant youth that he is not making a success of his work. Fired by a new hero—at nearly every stage of his career, if no real hero is about Martin finds it necessary to invent one—he pursues with zest for a time the career of assistant

medical officer of health. So long as his propagandist chief is about all goes reasonably well, but when the latter is translated to political life Martin fails to make good as his successor. He offends vested interests by hunting out carriers, annoys local practitioners by increasing the number of free clinics, and all the while his own lack of sobriety—this was before the days of prohibition—make him an easy prey to his enemies. Martin is favoured above ordinary men, for he gets a second chance to return, under Gottlieb, to the laboratory work which for years he has affected to despise. In this atmosphere neither his personal popularity nor his private life are of much moment, so long as his curiosity remains keen and he is able to test new hypotheses without bias. He works steadily for a period and takes well the disappointment of losing priority of a discovery of some importance. With an epidemic of bubonic plague in the West Indies comes the opportunity to test the curative power of a bacteriophage, the principle of which he had discovered independently of d'Herelle. With him travels his patient wife and one Sondelius, world-famed as a successful fighter against epidemics. In St. Hubert, the stricken island, comes the crucial test which Martin fails to pass. His creed bids him proceed, in the face of pity for the individual or care for the community, with the critical experiment sternly planned before his departure—to separate the afflicted into two batches, of which one only is to be given the phage. But when, after the death of Sondelius, who refuses treatment for himself because it is not freely offered to every sufferer, Martin's wife fails him for the first time by succumbing to the disease in his absence, he in turn fails to force himself to continue the experiment or to take any further interest in its progress. The plague subsides, and the expedition returns home to adulation carefully fostered by the institute which had financed it. Martin begs for a statistical investigation of his ill-kept notes before any conclusions are drawn, but his plea is suppressed and he has to bear congratulation on what he knows to have been a double betrayal. This is the crisis of his career. His subsequent marriage to a rich, charming widow and his ultimate abandonment of wife and child to embrace a secluded laboratory life appear almost an anti-climax. We cannot see him as a man who has at last learnt to know himself, but only as one who is too many-sided to find permanent satisfaction in any way of life open to him.

In an outline of the plan on which this, the best of Mr. Lewis's novels, is framed it is not attempted to do justice to the characters to whom he gives life. The tragic figure of Max Gottlieb is cast in a more heroic mould than Martin and is chiselled with a sure touch out of the essential rock of which men of science are made. Other studies are less finished, but all show an observation which penetrates through a man's spoken words to the thoughts which they are meant to hide. That these thoughts are often unworthy is not Mr. Lewis's fault; he must note what he sees, and those who fear to see it with him should avoid his books, for therein there is no escape. Relentlessly he analyses all that comes his way, gives few explanations, but allows his people to expose the conflicts from which they suffer in quick change from boastful self-satisfaction to humiliated confession. Mr. Lewis's own work has all the balance which his hero lacks; the scales are held fairly. The votaries of each branch of medical work, for example, are subjected on occasion to equally bitter if subtle criticism. If the men who hasten to claim therapeutic value for a new drug in the absence of adequate controls are held up to scorn, the pitiless inhumanity that will withhold from a sick person a remedy in order that a clean experiment may be recorded receives scant praise. Faked propaganda accompanying a "health week" is shown to be despicable enough, but life in a research institute is not pictured by contrast as a haven free from jealousy or importunity to premature publication. But if criticism is acute, appreciation is not lacking. The creeds of the healer,

of the propagandist, and of the searcher after truth are sacred in Mr. Lewis's otherwise ruthless hands, and the faithful who in the stress of life have lost a little confidence will be fortified by reading his book.

ISLANDS: WEST INDIAN AND ÆGEAN.

By Sir ARTHUR SHIPLEY, F.R.S., Master of Christ's College, Cambridge. London: Martin Hopkinson and Co. 1924. Pp. 139. 6s.

Sir Arthur Shipley, who is chairman of the governing body of the Imperial College of Tropical Agriculture in Trinidad, went out in 1923 to help to lay the foundation-stone of that institution. The College and its work form a considerable part of the material for the early half of the book, but, as Sir Arthur Shipley says, "it deserves to be prominent, as it is the first attempt to found an institution devoted to teaching and research in tropical agriculture." Anyone who reads Sir Arthur Shipley's lecture on tropical agriculture, given at p. 18 in his book, will realise the importance of the subject. The lecture was delivered at Georgetown, British Guiana. It will be news to many of us that the value of the annual yield of diamonds in the colony is about £1,000,000. We are also glad to note that the Hoatzin "must not be shot," for that singularly interesting survival of the reptilian age is a bird well worth preserving. His work done, Sir Arthur Shipley took his ease in Mr. J. Pierpoint Morgan's yacht in the Ægean, and gives a pleasant account of what must have been a pleasant cruise. Santorini in particular must be a fascinating

place, especially as vampires are abundant. We think that Sir Arthur Shipley is not quite just to the vampire, for he says that they have the power of bringing the dead to life and sending them forth to devour the living. According to the best authorities, a vampire has its origin from the suicide of a wicked man who forthwith becomes a vampire, rests in his grave by day, and comes out at night seeking victims who also die (apparently) but really become vampires in their turn. The burying the corpse of a suicide at the cross roads with a stake through the body, had its origin in the desire to prevent the birth of a vampire.

TROPICAL DISEASES BULLETIN. Vol. XXII., Nos. 1 and 2. 1925.—The first two numbers of this journal for 1925 contain an interesting series of communications. The January number of the *Bulletin* is mainly concerned with recent literature on dysentery, amœbiasis, and malaria. The two former subjects, comprising 62 papers, are summarised by P. H. Manson-Bahr, while Clayton Lane has reviewed an almost equal number of references to malaria. A. D. Bigland contributes a section upon native dietaries, and A. G. Bagshawe reviews papers on miscellaneous subjects.—The February number contains the third instalment of a review on Medical Helminthology by R. T. Leiper. Other subjects—beri-beri, scurvy, undulant and abortus fevers, Rocky Mountain fever, Japanese river fever, sandfly, dengue, and other fevers—are summarised by P. W. Bassett-Smith. The sleeping sickness section, by Warrington Yorke, completes the number.

NEW LUNACY ORDERS.

UNDER the title of "Statutory Rules and Orders, 1925, Lunacy, England," two important documents have recently been issued by the Commissioners of the Board of Control. The first of these consists of certain rules under the Lunacy Acts of 1890 to 1911, and is principally concerned with the way in which all books and records are to be kept. Details are set out with regard to the register of deaths, of discharges and transfers, of mechanical restraint and seclusion, and of boarders, along with the form in which nurses' reports and clinical records are to be kept. It is quite definitely set out who is to keep the various registers and who is responsible for the sending out of the notices on reception and on certain subsequent occasions. The periodical returns required by the Board of Control are also clearly specified, and the principal regulations with regard to licences, alteration in premises, plans of mental hospitals, &c., are described. The greater part of this publication,¹ however, consists of a schedule containing 30 forms indicating the manner in which the various registers are to be kept and skeleton designs for the report books and notice forms. The second of these two documents is a regulation, dated Jan. 7th, 1925, and deals with the mechanical restraint of lunatics.² Under Section 40 of the Lunacy Act of 1890 it is laid down that "mechanical means of bodily restraint shall not be applied to any lunatic unless the restraint is necessary for purposes of surgical and medical treatment, or to prevent the lunatic from injuring himself or others." Other clauses in this section refer to the records which must be kept of such restraint, and it is stated that "in the application of this section 'mechanical means' shall be such instruments and appliances as the Commissioners may, by regulations to be made from time to time, determine." This new regulation sets out the various instruments and appliances which may be used for this purpose. These are as follows.

(1) A jacket or dress, made of strong linen or some other strong material (a) laced or buttoned down the back having long outside sleeves fastened to the dress only at the shoulders, with closed ends to which tapes may be attached for tying behind the back when the arms have been folded across the chest; or (b) of some other pattern approved under the seal of the Board, a sample bearing the seal of the Board being in this case kept at the institution or workhouse for inspection.

2. Gloves without fingers, so fastened at the wrists that they cannot be removed by the wearer, and made of linen, leather (chamois or other), or some strong material padded or otherwise.

3. Sheets or towels, when tied and fastened to the sides or ends of a bed or to other objects.

4. If, in the opinion of the medical officer or medical practitioner who gives the certificate required by this section, some other mechanical means of bodily restraint is necessary in a particular case where the circumstances are exceptional, such means may be used with the previous sanction of the Board for such period as they may authorise.

It is pointed out that special supervision will be required in all these cases save in the form 2. The regulation goes on to describe certain procedures which are not to be considered as mechanical means of restraint but of which records must be kept. These include the continuous bath, the dry and wet pack, splints and bandages "used in accordance with recognised surgical practice," gloves so fastened as to be removable by the wearer, sheets or towels merely held and not fastened, trays or rails fastened in front of the chairs used by idiot children or the crippled and infirm. The Board are very anxious to make it clear in the concluding paragraphs of this regulation that they have by no means "given any greater countenance to the employment of this form of treatment than they have hitherto shown," and they urge that "the application of mechanical restraint should always be restricted within the narrowest possible limits, that it should not be long continued without intermission, and that it should be dispensed with immediately it has effected the purpose for which it was employed." This regulation comes into force on April 1st, 1925, and supersedes a regulation dated June 25th, 1913.

THE LANCET.

LONDON: SATURDAY, MARCH 14, 1925.

HEALTH STATISTICS IN THE MERCANTILE MARINE.

RECENTLY the President of the Board of Trade was asked in Parliament, by Mr. B. SMITH, whether he was in a position to prepare and supply statistics regarding health, as apart from mortality, in the Mercantile Marine service; whether there was a medical officer in his office and a special department dealing with problems of health and diseases in the service; whether the classification of diseases causing death issued by the Board of Trade could be brought into line with the more scientific classification adopted in the Royal Navy, and whether further information could be given regarding the population concerned, so that death-rates might be calculated. Sir PHILIP CUNLIFFE-LISTER replied that questions relating to the health and diseases of merchant seamen are dealt with by the Mercantile Marine Department of the Board of Trade in consultation with the Ministry of Health; that the Mercantile Marine Department has a staff of qualified medical officers; and that the question of modifying the classification of diseases in the statistics of the deaths of seamen issued by the Board of Trade is under consideration. As regards the preparation of statistics relating to the health, apart from the mortality, of merchant seamen, if the kind of statistics required were more precisely indicated, he would consider whether anything could be done. The Prime Minister, asked whether he would consider the transfer from the Board of Trade to the Ministry of Health of all questions affecting the health of seamen, said that the change would require legislation; he did not think the proposal necessary or desirable, since the Board of Trade was in close touch with the Ministry of Health on all matters affecting the health of seamen.

The answers of the President of the Board of Trade showed little appreciation of the complaints made against his department. If questions concerning the health of merchant seamen are dealt with by the Mercantile Marine Department of the Board of Trade in consultation with the Ministry of Health, are we to consider that the Ministry of Health approves of the grouping together, in the list of deaths, of tubercle and cancer as "constitutional diseases"? Again, though the Mercantile Marine Department may have a staff of qualified medical officers (including medical emigration inspectors), it does not follow that they are concerned with the health of seamen; no published evidence of the work of such officers appears. It is, at any rate, satisfactory to learn that the department is in close touch with the Ministry of Health, for this association should in future years increase our knowledge of the health of merchant seamen. What information we have at present on this subject comes from Part II. of the Supplement to the Sixty-fifth Annual Report of the Registrar-General, issued in 1908. Here, on p. 28, is a statement of the deaths of "occupied" merchant seamen in the three years 1900-02, by groups of ages, with a calculation of the death-rates for each age-group. For reasons stated in the supplement, no death-rate for the whole industry appears, but comparative mortality figures show that

for every 100 deaths among "occupied males" in England and Wales, there were 167 among merchant seamen, the figures for phthisis being 100 to 142, for pneumonia 100 to 153, and for accidents 100 to 458. No further table of this description has since been published, but unless conditions have greatly changed it would appear that to become a merchant seaman is to join one of the most unhealthy of occupations. Apart from the annual report of the Chief Medical Officer of the Ministry of Health, whose notes on the diseases of merchant seamen mostly discuss those diseases which are of international importance, we must go to the Board of Trade for what information there is to be had. In the annual "Return of Shipping Casualties to Seamen and Deaths on Vessels Registered in the U.K.," there is given in Table VI. the deaths by accidents, and in Table VII. the deaths by disease which have been reported during the year. The causes of death are not in every case certified by medical practitioners, but no other figures are available, and they are, we admit, useful for comparison with each other, since the errors may be presumed to work in the same direction from year to year. The records are by no means complete; it is not stated among how many seamen the deaths have occurred, and there is no figure in the returns by the help of which anyone could find out, however roughly, whether seamen had been, in any year, more or less healthy than in earlier years. 1921 was a Census year, and a Census of merchant seamen in British ships, at home and abroad, was taken on June 19th, showing: British 96,072, foreign 11,598, Lascars 44,241, total 151,911. The Board of Trade published these figures in 1923; but they are not included in the return for 1921, issued in 1924. Indeed, the returns seem to be designed on no definite plan, and to be compiled without any idea of what a useful medical return should be. In future it would surely be desirable, when the Board of Trade has collected from all over the world the figures of deaths, to forward them at once to the Registrar-General for publication; under Section 5 of the Census Act, 1920, new legislation would hardly seem to be necessary. The Registrar-General would group the diseases according to current methods instead of using a classification obsolete in all other Government departments except the Board of Trade.

The present inadequate presentation of the only statistics we have of the health of merchant seamen is, to say the least, unkind to the men of the merchant service. It is of urgent importance that more attention should be given to the deaths in this service. It employs some hundred thousand British seamen, most of them under 30, for the most part without any doctor to watch for and correct unfavourable conditions in their working lives. It is unseemly that the well-being of a group of men on whose activities our Empire so largely depends should be thus neglected.

THE SANOCRYLIN TREATMENT OF TUBERCULOSIS.

In a recent issue we dealt, from a biochemical aspect, with the salt sodium aurothiosulphate, isolated by Prof. MOLLGAARD and now being used in the treatment of pulmonary tuberculosis. The March number of *Tubercle* contains an original article on the clinical aspect of this treatment by Dr. J. GRAVESEN, medical superintendent of Vejlebjerg Sanatorium, Denmark. The article in question consists of a discussion of the toxicity and action of the substance, with the special indications for the selection of cases,

a description of complications met with, and some preliminary clinical results. With regard to toxicity, Dr. GRAVESEN is careful to point out that there may be difficulty in distinguishing between those clinical signs and symptoms which are due to the metallic poisoning of the salt and those which are due to circulating toxins liberated by the supposed bactericidal action of the gold salt on the tubercle bacillus. This difficulty of interpreting the signs of toxicity of the salt is apparently a real one, and while admitting that some of the earlier signs are probably "biotoxic," to use his own phrase, the author is careful to point out that the later appearance of albuminuria, digestive disturbance, metallic taste in the mouth, and desquamative dermatitis and stomatitis are to be credited to the metallic poison action of the salt. Dr. GRAVESEN has, however, no doubt that sanocrysin exerts a specific action upon tuberculous subjects in therapeutic doses, though we are not quite clear in what sense he uses the word specific. As an antidote against toxæmia an anti-serum is used, prepared from animals immunised with diaplyte tubercle vaccine. It is here that one of the serious difficulties of the treatment would appear to arise, for although the serum is stated by Dr. GRAVESEN to have certain protecting power it does not adequately neutralise the toxæmia, and as he points out, much more work is necessary on this side of the question before sanocrysin can be generally applied to the treatment of tuberculosis. Anti-sera in this disease have never been found satisfactory from a clinical point of view. At least three different anti-sera appear, so far, to have been used in connexion with sanocrysin experiments—namely, the serum of a spontaneously infected animal, the serum of an animal immunised with dead bacilli, and, finally, a serum of an animal immunised with defatted bacilli. In some cases the administration of an anti-serum has been tried before sanocrysin treatment. A further difficulty arising from the danger of toxæmia is found in the choice of suitable cases. In discussing this matter the writer makes use of the classification of RANKE, which is not commonly used in clinical medicine in this country. Thus, he divides his cases into exudative and proliferative. The former are acute toxic cases in which the pathological picture is presumed to be that of acute exudation and tissue destruction; the latter are chronic cases with new-formed tuberculous granulomata and chronic proliferation of fibrous tissue. The recent exudative types are considered much more suitable for sanocrysin treatment than the chronic proliferative cases. In other words, the more fibrosis the less the probability of effecting a good result. From this it would appear, clinically, that the chronic case with large thick-walled cavity, which is a common type of case met with, does not react well to treatment. Cachexia also is a contra-indication. Pyrexia, on the other hand, is not necessarily so, since it may be merely an outward and visible sign of what Dr. GRAVESEN calls "the recent exudative type."

As is customary with all new remedies of this kind, the question of dosage is difficult to determine, and Dr. GRAVESEN considers that no general rule can be laid down, but that each case must be judged on its merits. This is an obviously sound old rule. In serious cases the initial dose used has been as low as 12.5 cg., whilst the maximum dose in favourable cases has been 150 cg. The interval between doses varies from two to six days according to the general condition of the patient and the effect of the drug, the ultimate aim being the administration of a full dose without recourse to the protective action of serum. The complications noted are: general reactions of fever,

anorexia, nausea, diarrhoea, albuminuria, and focal reactions leading to temporary or permanent reactivation of the lesion. Glands also may temporarily increase in size and tenderness, and the author records one case which was followed by abdominal tuberculosis and a pleural effusion. Some of these disturbing reactions appear to be not unlike those which we used to get in the early days of the tuberculin era when large doses were given. To these must be added signs of metallic poisoning, which may be counteracted by careful attention to the mouth and teeth, and the omission of any drugs such as bromides or arsenic leading to harmful combination with the salt. It is apparent, then, that the treatment can only be used with great care and watchfulness, especially in view of the difficulty in deciding whether the toxic symptoms produced are due to the effect of liberated toxins or to metallic poisoning. At this early stage Dr. GRAVESEN is guarded in his estimate of results. He gives a short table summarising these in 44 cases. Of these, 22 he considers negative, the patients having remained stationary, become worse, or died; and 22 he regards as positive, with apparent cure, much improvement, or improvement. He further suggests that the treatment may offer some scope in combination with other special forms of treatment, such as artificial pneumothorax or thoracoplasty. To quote his own words, the writer sums up by saying: "I am convinced that we have in sanocrysin a real chemospecific with an action, hitherto unknown in tuberculosis, upon certain suitably selected cases." The italics are our own, since they appear to us to qualify materially the use of the word chemospecific.

It is interesting to compare these results with those given in the book recently published by MOLLGAARD and his co-workers on the Chemotherapy of Tuberculosis. Here G. E. PERMIN reported 15 cases of pulmonary tuberculosis, of whom six died; whilst of the remaining nine, five were unchanged and four seemed to be undoubtedly improved. K. SECHER recorded 15 cases of tuberculous pleurisy, 14 of whom did well, whilst the fifteenth subsequently died of tuberculous peritonitis. He also gave details of two cases of tuberculous peritonitis, one of whom did well and the other died. In children V. BIE, K. SECHER, and C. H. WÜRTZEN reported six cases of tuberculous adenitis, all of whom became free of symptoms; and 16 cases of pulmonary tuberculosis, 12 becoming free of symptoms, 1 improved, 2 unimproved, and 1 worse. OLE CHIEVITZ recorded a series of cases of surgical tuberculosis with the following results: 35 cases were treated; 3 were healed, 3 improved, 27 unimproved, and 2 became worse. K. SECHER collected a series of cases of pulmonary tuberculosis. Of these, 9 early cases without bacilli and 3 early cases with bacilli all improved. Two more advanced cases became free from symptoms and 7 improved. In 10 cases treatment was abandoned, whilst of three cases of miliary tuberculosis of the lungs one was reported as well, the second improved, and the third abandoned. Nine pulmonary cases were reported as having died after treatment. Finally, there was an extensive series of cases by C. H. WÜRTZEN, the results of which were not tabulated, though the cases were reported in full. Throughout the book the large numbers of cases recorded were quoted in the fullest and frankest manner, but the analysis of results is not always easy to follow, presumably because the authors were anxious, at this early stage, to present plain facts rather than hasty deductions.

It is clear that there are many issues raised by sanocrysin treatment which need to be cleared up before a final judgment can be offered, and it is

important that the treatment should not be boomed as a cure for tuberculosis until these issues have been carefully worked out. In the first place, the question of toxicity is a complicated one. Some of the toxic symptoms produced are certainly those of metallic poisoning; others which are claimed to be a result of liberation of tubercle toxin are perhaps more difficult to explain, whilst there is yet a third factor in toxicity—namely, the so-called tuberculin shock which has been described in a few cases. Careful experiments are also needed on such questions as the accumulation of the drug in the tissues, especially in such organs as the liver, spleen, kidneys, and lungs. It has been found, for example, in previous gold salt experiments, that this accumulation may take place far in excess of the concentration needed to destroy the tubercle bacillus in vitro, without satisfactory clinical results being achieved. Side by side with these considerations there is the question of the rate of elimination of the drug by the usual channels. All these questions must have an important bearing on dosage and the spacing of doses. Finally, the protective use of an anti-serum involves us in a whole set of new problems. Bacteriologists have hitherto been profoundly dissatisfied with the anti-sera advocated in the treatment of tuberculosis, and the possibility of combining an anti-serum with a chemo-therapeutic inoculation is certain to provoke much discussion and experiment. From the evidence so far published we do not feel prepared to agree with Dr. GRAVESEN in speaking of sanocrysin as a chemo-specific for the treatment of tuberculosis, though we are well aware that this term possesses many shades of meaning; perhaps for this very reason it would be better at the present stage to avoid the use of the term.

DOMESTIC HELP AND NATIONAL WELFARE.

IN a complex society such as that in which we have our being it is difficult to forecast the reverberations which may be aroused elsewhere by a sudden alteration in any one part of the economic fabric. When the principle of relief in money to the unemployed was established to meet the conditions produced by the trade depression of 1919, few could have foreseen that such a step would have any but beneficial results upon the present health and future well-being of the nation as a whole. As matters are now shaping the reverse promises to be the case. According to the most recently published figures from the Ministry of Labour, some 230,000 women and 50,000 girls are at present in receipt of the "dole." That is to say, over a quarter of a million women, many of whom under other conditions would cheerfully be lending their aid to the housewives of the nation, are now definitely withdrawn from the labour market in so far as domestic service is concerned. That such a state of affairs should result in a deficiency of domestic help is obviously inevitable. That this should react upon the present health and future well-being of the nation is not so immediately obvious—in fact, by some of the more short-sighted Members of the late Parliament it was publicly pronounced to be a matter for gratulation that the mothers and wives of this country were now having to fend for themselves. Two immediate effects, however, are resulting from this shortage of domestic help, both so plainly and so universally evident in the life of the people that the tendency has been

rather to refer them to that peculiar category of phenomena known as "signs of the times" than to seek for their obvious explanations. The two domestic activities most consuming of time and labour are the bearing and nurture of children and the preparation of food; in the absence of domestic help it is in these two directions that that portion of the population which is accustomed to depend upon its own efforts for its subsistence has had to curtail its activities.

The fall in the birth-rate of what may be spoken of as the self-supporting class in contradistinction to the State-aided, is a phenomenon so striking that it has attracted the attention of sociologists and moralists alike. Many factors are undoubtedly at work to produce it, but five minutes intimate conversation with any young married couple of the self-supporting class will reveal the fact that one very definite reason for this curtailment of the size of the family is the difficulty, under present conditions, of securing that domestic help which is necessary for the care of a large family of young children. There is a feeling among a certain class of doctrinaires that the family is a unit and should in a properly organised state of society be entirely self-contained. Oddly enough, the holders of this individualistic dogma are to be found among those most favourable to communal effort in other directions. It is sufficient to point out that the "family," consisting of husband, wife, and children, never has, and never in the nature of things can be, an entirely independent unit. The bearing of a child may roughly be regarded as removing a woman for six months from the efficient performance of other domestic activities; the plunging of the mother into the full tide of household life at an earlier date can only result in harm to herself or her offspring. In that primitive state of society which may roughly be described as patriarchal, the influence of which even in the industrialised portions of the world still persists, the child-bearing woman had the assistance of a numerous retinue of aunts, sisters, and other more distant female relatives not immediately concerned in the same business, not to mention in an earlier world slaves and other female retainers bond and free. With the gradual disappearance of the patriarchal system and the establishment of the custom of an immediate departure from the parental roof of the newly-married couple reliance had come to be placed upon paid servants. Now that these are not forthcoming the only solution that has so far presented itself is severe limitation of the size of the family. The inevitable decrease in the self-supporting portion of the population, with an accompanying proportional increase of that section accustomed to look to the State for maintenance, is a prospect hardly to be faced with equanimity. Intimately connected also with the shortage of domestic help is the problem of combating the harm done by the adulteration of food. Attention has recently been drawn to the danger of preservatives in food. From no standpoint save that of economy of time and labour can any form of preserved food be regarded as equal in value to the freshly prepared article, and presumably no one would eat it in preference to fresh food. None the less, the consumption of preserved comestibles of all sorts shows a steady increase. It is hard to believe that this increase is due to any large extent to a gross growth of laziness in the general population; there can be little doubt but that the principal factor is the difficulty of procuring help in the kitchen.

The process of adaptation to the new social conditions has yet hardly commenced and it is difficult to see in what direction it will proceed. The obvious solution would appear to be a relaxation of the bonds of individualism and the development of a communal system of welfare centres, creches, kitchens, and so forth, for the benefit of those who are able and willing to pay for them, on similar lines to the system now at the disposal of those who are served gratuitously.

Annotations.

"Ne quid nimis."

THE SALARY OF A SCHOOL MEDICAL OFFICER.

THE West Riding County Council are advertising in the daily newspapers for assistant school medical officers at a commencing salary of £500 per annum. The terms are below those arrived at by the British Medical Association and the Society of Medical Officers of Health, at whose instance, supported by THE LANCET, local authorities have been advised for some time that the commencing salary for a whole-time assistant medical officer in a public health department should be £600. Recently, by invitation of the Ministry of Health, representatives of the B.M.A. and of the Society of M.O.H.'s met delegates from the bodies representing local authorities to discuss the matter of salaries in the public health service. As one outcome of the negotiations, the Ministry advised the County Councils Association, the Association of Municipal Corporations and kindred bodies that the £600 minimum might be accepted as not unreasonable for assistant medical officers with adequate qualifications and experience, and it has been postulated that candidates for these posts should have had at least three years' practical experience. Seeing that over 80 appointments have been filled on the £600 basis during the last 12 months, it was thought that there would be no further dispute in regard to appointments in this category. The West Riding advertisement states that the school medical officers appointed at £500 will receive annual increments of £25 up to £650, but this method of advancement has not the practical advantages that it wears, for having reached the maximum the medical officer will have only remote prospects of promotion, there being but few administrative posts in the school medical service. Candidates who may be tempted to accept these appointments for the sake of their immediate convenience should look ahead, visaging a time when they may be in a less favourable position for choosing a more profitable branch of practice, and when their domestic obligations may be increased. We hope that it is not too late for the West Riding County Council to revise the terms of their advertisement, so that medical men and women of good standing and varied experience may feel justified in applying for the posts, for they must realise the importance of securing school medical officers who can command the confidence, not only of the education authority, but of the private practitioners with whom their work brings them in daily contact.

AVIATION AND MEDICINE.

At a meeting of the Royal Aeronautical Society on Thursday, March 5th, Lieut.-Colonel C. B. Heald, Medical Adviser to the Department of Civil Aviation, delivered a lecture on Some Medical Aspects of Air Transport. He pointed out that the medical questions of aviation were of interest not only to those directly concerned with flying—pilots, insurance companies, and the air-travelling public, and to the whole medical profession—but to physicists generally; for in aviation, he said, we are dealing for the first time, so far as the history of mankind reveals, with life and work in three dimensions, and we are learning previously unknown facts about the mental and physical make-up of people subjected to strain and stress in a new environment. The medical work of civil aviation is not confined to the routine examination of pilots, although this naturally forms an important part of such work, but it has to take into consideration all matters concerning the general life of those associated with civil air transport, and all the general questions of hygiene and health organisation that help to build up comfortable and efficient

services. Colonel Heald gave a detailed description, illustrated by lantern slides, of tests employed on the medical examination of the pilot, and dealt at some length with the more general aspects of the career of the airman and the factors which influence his health and lasting powers. From these considerations some important facts emerge, showing that the estimation of complete fitness in flying men has given to clinical medicine a new viewpoint. And at this point the lecturer concluded that the measurement of physical conditions, as distinct from the detection of disease, demands a new technique, when results of a value as yet unreckoned may be clear. Colonel Heald believes that this new technique for estimating physical efficiency—in what manner each system of a particular individual will endure and function under stress and strain for that individual—will come, directly or indirectly, from our improving knowledge of electrical phenomena and the ultimate composition of matter, the outstanding features in the progress of medicine to-day being chiefly electrical. Colonel Heald's prophetic vision will not be dismissed as a baseless flight of fancy because a recent demonstration before two sections of the Royal Society of Medicine made clear only one thing—namely, that the subject was unready yet to leave the physical laboratory. Medicine, grappling with the problem of deciding the fitness of a man to adapt himself to a new element, has found that the criterions of health may not lie wholly in the stethoscope and sphygmomanometer, and Colonel Heald is logical when he says: "It would surely, therefore, be fitting if through this new science of aviation we should find our feet set on a new pathway, leading possibly to a definite understanding of those forces that Sir Oliver Lodge, Prof. Richet, and the late Sir James Mackenzie have already sensed."

BONE METASTASES IN CARCINOMA OF THE BREAST.

THE vagaries of the dissemination of carcinoma are difficult to explain on any simple hypothesis, and it would seem that almost necessarily there must exist a number of causal agents for malignant disease. Secondary growths in bone are fairly common when the primary lesion is in the breast, the prostate, or the thyroid, but very rare when for instance it affects the tongue. Again, one case of breast cancer will produce widespread secondary nodules in its neighbourhood and in the axillary glands, whilst another remaining quite small itself will give rise to numerous remote metastases. Sir George T. Beatson, in the current number of the *British Journal of Surgery* (1925, xii., 473), reports a case of carcinoma of the breast in which there were multiple bone lesions. The woman lived for six years with the carcinoma before symptoms sufficiently severe to worry her appeared. Then she began to suffer from pain in one leg and a loss of power of the arm on the affected side. Pathological fracture of the clavicle, femur, and humerus occurred before her death about one year later. Post mortem were found metastases in all the long bones of the limbs, the clavicles, and certain of the ribs and vertebrae. There were numerous growths in the phalanges of the hands and also in one of the metatarsal bones. The interest in the case lies in the demonstrated likelihood that these secondary growths were conveyed from the breast by the blood-stream, for permeation of the lymphatics could scarcely be invoked to account for the metastases in the foot. Another curious feature was the fact that the sternum in the direct permeation path was quite free from growth. Additional evidence of blood-stream infection was the state of the lungs through which of necessity all emboli must pass to reach the systemic circulation, for they were found to be studded all over with small metastases. It was also observed that the growths in the liver seemed to have originated in the deep parts of that organ and not in the periphery, as the permeation hypothesis of spread would demand. Union of the

fractured clavicle occurred, but this is not real evidence of repair in a malignant growth. Patients who have suffered a pathological fracture of the femur secondary to breast cancer have even been known to get union and walk for a time. The simplest explanation is that only a portion of the thickness of the bone was destroyed by the growth. The remaining unaffected area, after fracture, was able to throw out so much callus as to form a support of weight bearing capacity. It has been frequently observed that bone metastases occur in cases where the original growth is quite small, so it would be of great practical importance to be able to ascertain whether the bones are affected or not when the patient seeks surgical aid. According to A. Piney¹ certain characteristic blood changes occur when the growth invades the bone-marrow, by which this invasion can be recognised. Whilst this statement is true in some cases, it does not seem to be so invariably; the characteristic blood picture was absent in the case under discussion. It is, however, important on occasion to make the blood examination, for positive evidence might show that operative interference would be useless.

THE PRESENT POSITION OF THE DENTAL PROFESSION IN ITALY.

WE have received from Dr. F. Montuschi, dental surgeon to the Italian Hospital, a report on the recent legislation in Italy to regulate the practice of dentistry. The Royal Decree of Oct. 16th, 1924, made the possession of a degree in medicine and surgery compulsory for the practice of dentistry. This compulsion dates back 34 years from the Boselli decree, but subsequently all those who had practised dentistry by virtue of minor diplomas granted by various universities continued to do so and, as is the case now in England, many who had practised without a diploma were allowed to continue after an examination in the subject. The Boselli decree did not become law until 1912 with the concurrence of both branches of the legislature. There was, however, in Italy an absence of good schools for the teaching of dentistry and such medical men as wished to practise it conscientiously were obliged to go abroad. Many of them came to our Royal Dental Hospital until the foundation of three dental institutes at Milan, Bologna, and Florence, each of which has a curriculum of one year's duration. In Rome a small but influential group continued to ask for a doctorate in dentistry independent of medicine and surgery, somewhat after the type of the American D.D.S. They wanted the medical student after his fourth year to relinquish his studies and join the school of dentistry and dental mechanics which was to be established in Rome, and after a curriculum of two years to pass an examination which would confer on him a doctorate in dentistry and dental prosthesis. These ideas found sympathy from the Minister of Public Instruction in Signor Mussolini's Cabinet, who, owing to the full powers conceded by Parliament, secured at the end of 1923 the approval of the Council of Ministers for a decree establishing a national school of dentistry and dental mechanics in Rome; this meant the institution of a degree in these subjects at the end of the prescribed course of study and the passing of a special examination. This decree aroused violent opposition, as medical opinion had pronounced in favour of a compulsory degree in medicine and surgery for dentists. Augusto Murri wrote expressing his views as to the indivisibility of dentistry and general medicine and advocating that the former must be considered as belonging to the same category as other medical specialties, and a few months later the Minister who had approved of the decree was replaced by Senator Casati; then the Mussolini Cabinet rescinded the decree and substituted a new one which re-affirmed the principle of a compulsory degree in medicine and surgery for the practice of

dentistry. The new decree stiffens the statute of March 31st, 1912, since it not only requires all dentists to be previously qualified in medicine and surgery, but enjoins upon all future medical practitioners the undergoing of a practical test in dentistry and mechanics to enable them to practise the art of medicine. It is not that the medical graduates of the universities, to which the new statute allows freedom in regulating their special studies, will all be finished dentists, but they will at least know enough to guide them in investigating each case and adopting proper treatment, especially in rural districts where there is no expert dentist.

In Italy the future medical practitioner will have a knowledge of the fundamentals of dental science, as he has of ophthalmology and dermatology. For dentists in the future—i.e., medical specialists in dentistry and prosthesis—the general university reform actuated by Gentile efficiently provides in the same way as it does for all other specialists. This measure enjoins that no one can arrogate to himself the title of "specialist" in any branch of medicine without having acquired the relative diploma granted by each university. Anyone who does not conform to this rule will be suspended from practising, so that in the near future the public will be able to distinguish the true from the false specialist. In fact, this same reform allows each university to establish special post-graduate schools in any subject, equipped for granting, after examination, specialists' diplomas. As far as dentistry is concerned, there already exist in Italy the three dental schools of Milan, Bologna, and Florence with a yearly curriculum; and now, in order to march with the times, these have profited by the present didactic legislation and have biennial courses, while other schools will of necessity spring up. Italy will thus be the first among progressive nations to require all medical practitioners to know at least the principles of dentistry and dental mechanics and to insist that all who practise other medico-surgical specialties shall, after having obtained their degree, pass a special examination which will be proof of a real knowledge of the specialty they intend to practise.

THE EYES IN HOT CLIMATES.

IN a paper on Ophthalmology in Egypt, read at a recent meeting of the Section of Tropical Medicine of the Royal Society of Medicine, Mr. A. F. MacCallan, at one time Director of the Egyptian Government Ophthalmic Hospitals, gave some valuable instruction on the care of the eyes in hot climates. While fatigue, ill-health, and worry bring out latent defects in the eyes in any country, a hot climate causes greater fatigue than a temperate one, and this fatigue, he pointed out, may lead to fatigue-indigestion with resulting physical depression. Worry, whether of official or of private origin, similarly may cause ill-health. Under these conditions he found that trifling errors of refraction, or slight degrees of heterophoria, exerted effects quite out of proportion to their actual severity, and he emphasised the importance of careful correction of these errors, generally under a cycloplegic such as homatropine. In a highly sensitive patient, whose nerves were constantly being jarred by physical or mental discomforts, the correction of a very small degree of astigmatism might make all the difference between happiness and misery. In a country such as Egypt, the healthy emmetropic eye of the European becomes painfully affected by the sun's glare in the summer when motoring or riding along dusty roads or over the desert. It is the heat rays from the red end of the spectrum which cause this. To prevent the effects of glare, Mr. MacCallan advises the wearing of protective goggles of Crookes B or B2 material; but if discomfort is complained of the refraction of the patient should be verified under a cycloplegic. There are, he states, other varieties of protective glasses, which theoretically are more absorbent of the heat rays than Crookes glasses, such as peacock

¹ Brit. Jour. Surg., 1922, x., 235.

blue, Fieuzal, and amber, but in his own experience of a large number of cases he found that ordinary glass in which was included, if necessary, a very small ametropic correction, was all that was required. Sun, dust, and wind might also cause pinguecula and pterygium. In dusty seasons it is most advisable to wash from the eyelids the dust which collects there and which may contain septic material. This should be done three times a day. In many cases he found this simple precaution sufficient to prevent constantly recurring attacks of conjunctivitis.

SURGICAL TREATMENT CENTRES.

THE medical profession and the lay public are alike apt to associate the Ministry of Pensions with medical boards and claims and awards rather than with any idea of treatment of war disabilities. The article which we publish in another column by Dr. C. V. Mackay and Mr. D. D. Pinnock on the treatment of war injuries at special surgical clinics, dealing with this lesser known but very important side of the Ministry's activities, shows that valuable work is still being done up and down the country in the treatment of those disabling effects of the war which in so many cases continued for a long time after the crippled men left the services. The organisation and work of these special clinics are clearly set out. It will be seen that the whole scheme is closely linked up with the surgical hospitals of the Ministry of Pensions and with the centres for the provision of surgical appliances and artificial limbs. Existing facilities at civil hospitals have also been utilised, and it will be seen that every encouragement is given to pensioners to make use of the treatment thus offered by the payment of travelling expenses and of allowances for time lost from work on account of treatment. Apart from the clinics at civil and Ministry hospitals, surgical treatment centres have been established in various parts of the country at the following places:—

Northern Region.—Bishop Auckland, Bradford, Carlisle, Hull, Stockton, Sunderland.
North-Western Region.—Birkenhead, Manchester.
Midlands Region.—Birmingham, Coventry, Nottingham.
South-Western Region.—Bristol, Exeter.
London Region.—Brighton, Westminster, Camberwell, Tooting, Portsmouth, Reading, Southampton.
Scotland Region.—Aberdeen, Dundee, Edinburgh, Glasgow, Kirkcaldy, Stirling.
Wales Region.—Bridgend, Pontypridd, Wrexham.

The majority of these clinics deal also with the supply of surgical boots and appliances. In addition to these centres, the British Red Cross Society has also established "Curative Posts," for the benefit of ex-Servicemen, which are recognised by the Ministry of Pensions. For example, in the county of Surrey alone five were established by the county branch of the British Red Cross in 1919. The posts are fully equipped with electrical apparatus, and in some cases X ray photographs can be taken. The voluntary staff consists of an officer in charge, an almoner, registrar and treasurer, and V.A.D. helpers. The professional staff consists of a medical officer, one or more trained nurses, and a varying number of masseurs and masseuses according to the number of cases on the books. Since the diminution in the number of ex-Service patients the posts have been used for civilians, to the great benefit of the inhabitants of the various towns and villages concerned. The payments from civilian patients are supposed to vary from 2s. 6d. to 10s. 6d., the latter for several treatments combined, but unfortunately all patients are not able to afford even the minimum charge, and in these cases various expedients have to be resorted to; under certain conditions the funds of the branch are used to supplement the payments. Two of the posts, Woking and Kingston, have also opened orthopaedic clinics for children under the care of an orthopaedic surgeon from a London hospital who makes periodical visits. These are said to be a great success, and the medical officer of health reports that the Surrey

County Council consider it to be one of the most satisfactory services in the county. A good number of children from the London hospitals are treated in the Surrey posts, some of these attending their own surgeons at the London hospitals. The County of London branch established similar clinics in 1919 and at one time there were 13 such treatment centres for disabled ex-Service men in various parts of London. With the decrease in the number of men requiring treatment certain of these centres have been closed and only five remained at the end of 1924. In February, 1922, a civilian clinic was opened in Kensington to meet the needs of those who are unable to afford the full fees obtaining for massage and electrical treatment. A maximum fee of 5s. per treatment is charged, the fees graduating down to 1s. 3d. per treatment. Towards the end of 1924 a similar clinic was opened in Hackney. From this brief summary it will be seen that the treatment aspect of war disabilities is receiving the consideration it warrants from both voluntary and official bodies, and the extension of the Red Cross Society's activities to civilian patients forms an important and interesting development.

THE ANATOMY OF TWINS.

TWIN bodies of the uniovular type do not often come to the anatomist for examination. Hence not much is known with certainty or conclusive definiteness about the relations existing between the twins of this form, and the views advanced from time to time about the cause of twinning are little more than assumptions adopted to fill the void of ignorance on the subject. The theory of polyspermy as a cause is an example of such assumption; it is probably quite unsound and untenable from the nuclear and cytological point of view, and it can be pointed out that, in animals in which polyspermy normally or frequently occurs, the additional spermatozoa are non-effective to all appearance, while in a case like that of the armadillo, in which normally more than one embryo is formed from a single ovum, there does not seem to be polyspermy. All that can be said with certainty is that the uniovular twin is an end-product of the process of dichotomy affecting the embryonic contents of the developing ovum, and the cause of its occurrence will be known when the explanation and meaning of dichotomy is understood. The result of dichotomy may be incomplete or complete division, and, in its axial form, ranges from the parasitic foetus and other monstrosities, through the partially attached individuals to the completely separated twins. In this last case the embryonic division may stop at this point, leaving the amnion undivided, or may even involve this, so that each individual possesses his or her own amnion. It is theoretically conceivable that the dichotomous process, beginning at the earliest possible moment, might lead to complete division of the whole ovum, so that each foetus would have its own chorion and placenta; but the occurrence of such a condition has never suggested itself to any observer, and a single chorion and placenta may thus be considered a proper accompaniment of uniovular twins. This, in fact, seems to be the most valuable criterion, in practice, in deciding on the nature of twin births. Those of opposite sex are not uniovular; when of the same sex they may or may not be so, but when they are enclosed in a common chorion, or—the same thing—have a common placenta, they are uniovular. When such details as these are lacking in the birth history, it is not possible to give more than the negative pronouncement that twins of different sex are not uniovular. The subject of twins is always fascinating, and Prof. G. R. Murray, in a presidential address published in this issue of THE LANCET, has ranged far afield and gathered many little-known items of information on the subject. Prof. Murray refers to one matter, the occurrence of *situs inversus* in certain individuals, which, in the past, has perhaps had more value attributed to it than is justifiable. It has been

found in some twin monsters, occasionally in separate twins, and on this the theory has been broached that this condition, when found in an ordinary individual, probably points to his being the surviving member of a twin formation, the other member having failed to develop, or having disappeared in some other way. On this theory a sort of imaginary vicious circle was easily established, and many believed that *situs inversus* in one of the twins was the normal thing. This is not so, though we cannot say how often or under what conditions it may occur. There is a tendency, more marked in other countries than England, to refer such happenings to variations in axial and other gradients, which are, in one sense, matters of metabolism. For those who see in such gradients evidences of cause rather than a complicated expression of process the explanation of morphological differences appears fairly easy, but in any case more data are required about the percentage occurrences of these differences. Moreover, the theoretical possibility hinted at above, that a still more complete division of the ovum might lead to formations apparently not uniovular, should not be ignored. Those who do many post-mortem examinations on women do not, we believe, hold the usual views about the frequency of ovulation, and, if the complete division of the ovum could be established, the frequency of twin formations would come more into line with the apparent frequency of ovulation. Skilled observation of numerous specimens of twin formations is required, however, and practitioners able to furnish such specimens—preferably complete, but at any rate with details of birth history—would be doing good work if they were to send them to an anatomist; nothing is gained by sending them to the pathologist, for they are normal developmental specimens, and the anatomist only wants material to enable him to furnish data on which more reliable hypotheses than those at present current may be founded.

WE regret to announce the death of John Cleland, F.R.S., M.D. Edin., emeritus professor of anatomy in the University of Glasgow, in his ninetieth year, at Moorcroft, Lidsing, Chatham, on March 5th. Prof. Cleland held the chair of anatomy in Glasgow from 1877 until his retirement in 1909.

ON the recommendation of the Secretary of State for Scotland, the King has approved the appointment of Mr. John Fraser, M.C., to be Regius Professor of clinical surgery in the University of Edinburgh, in room of Sir Harold J. Stiles, whose resignation takes effect on March 21st. Mr. Fraser graduated with honours at the University of Edinburgh in 1907, gained the Ch.M. with honours in 1910, and was awarded a gold medal for his M.D. thesis in 1912. Among other appointments he holds is at present that of assistant surgeon at the Royal Infirmary, and surgeon to the Royal Hospital for Sick Children, Edinburgh. He is also a university lecturer on diseases of children, and lecturer in systematic surgery to the School of Medicine of the Royal College of Physicians and Surgeons of Edinburgh.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The twentieth meeting of the Commission was held at the Home Office, Whitehall, on March 5th, Sir Andrew Duncan in the chair. The National Conference of Friendly Societies, represented by Mr. J. W. Shaw, Mr. Alfred Saunders, and Mr. William Marlow, gave evidence on the question of a public medical service to replace the medical and other treatment benefits given under the insurance scheme. Evidence was given on behalf of the Royal Insurance Officials Benevolent Association by Mr. Duncan Fraser and Mr. E. Syder relating to the general work of the Society and in particular to the application of surplus. Thereafter the Incorporated Dental Society, Ltd., represented by Mr. W. F. Bowen and Mr. F. Butterfield, was heard on the question of making dental treatment a universal benefit, and the scope, administration, and cost of such a benefit. Proof copies of the oral evidence and the relative statements submitted at the meeting of Feb. 19th are now on sale at H.M. Stationery Office (2s. 3d.).

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXIII.

THE TREATMENT OF MISPLACEMENTS OF THE UTERUS.

UTERINE displacements fall naturally into two large classes according as the displacement is backwards or downwards, though it must be remembered that the two are often coexistent. It is not within the scope of this article to discuss the causation of these abnormal positions of the uterus, but rather to indicate the modern ideas of the means best suited to remedy them. These means may be educative, mechanical, or surgical, and there are certain indications for the employment of each of these methods. Again, the treatment may be palliative or curative, according to the general condition or the wish of the patient herself. In this article it is proposed to consider: (a) backward displacements—either retroversion or retroflexion, or both combined; (b) simple prolapse; and (c) prolapse together with retroversion. Common to all three is the principle that treatment is only indicated when the symptoms complained of can be definitely ascribed to the malposition present. There is undoubtedly a tendency to assume that a displacement of the uterus is giving rise to symptoms, when in fact it has no part in the production of the clinical picture presented. Very careful consideration must be given to the individual case in order that the relation between the abnormality discovered and the symptoms complained of may be properly determined. An example which might be cited is the comparative frequency with which menopausal symptoms are ascribed to uterine misplacements, with subsequent disappointment when measures for the relief of the misplacement are not followed by any mitigation of the symptoms.

Backward Displacements.

Controversy rages around every aspect of the treatment of these conditions, and it is difficult to present a succinct and reasoned view of the present position. In my opinion congenital backward displacement is but rarely accompanied by symptoms which call for treatment.

Congenital Backward Displacement.—When such symptoms do occur in congenital cases, it is reasonable to attempt to satisfy oneself that a correct position of the uterus would cure them; therefore a trial should be made of replacement, if necessary under anaesthesia, and the use of some form of pessary. If by these means the symptoms are relieved, it is legitimate to suggest that some permanent steps should be taken to keep the uterus in a normal position. It has frequently happened in my experience that a retroversion, probably congenital, has been found in cases of sterility or of repeated early abortions. In such cases I suggest that replacement and a pessary be tried before any further line of treatment is advocated. Particularly is the risk of early miscarriage minimised if the retroverted uterus be gently replaced as soon as pregnancy is known to have occurred, and a soft rubber pessary be worn for the first three or four months.

Backward Displacement of Acquired Origin.—These cases usually date from a confinement, though one has seen cases in which a traumatic origin has been probable. The routine examination of patients six or eight weeks after confinement should make it possible for a number of these acquired cases to be recognised and treated early, and it is probable that many of them could be cured by simple means. When discovered in retro-position the uterus should be replaced and a pessary of appropriate shape inserted. The patient should then be carefully

instructed as to three points: (1) the regular emptying of the bladder; (2) the prevention of constipation; and (3) the efficacy of lying on the face for a time every day. At the end of three months the pessary is removed and in a fair number of cases no further symptom develops.

In cases of longer standing in which the symptoms call for treatment, the effect of replacement and a pessary should also be tried, and operation reserved for those cases in which the uterus cannot be replaced or in which the pessary and the replacement have been followed by a definite relief of symptoms. When operation has been decided upon an essential point is to leave the uterus in an approximately normal position, and in my opinion a curettage does not fulfil the conditions for a cure. The relief experienced after dilatation and curettage does not last, and many patients suffer a return of their symptoms after a shorter or longer interval.

As to the operation to be practised for the permanent replacement of a retroverted or flexed uterus it is difficult to be dogmatic. Numberless varieties of operative technique have been devised, falling into groups: (a) Suspending the uterus from the parietal peritoneum; (b) fixing the lower part of the anterior wall of the uterus to the anterior abdominal wall; or (c) sing the round ligaments as a means of slinging the uterus in its normal position. The second and third varieties alone have claims to serious consideration, the second in spite of M. Dartigues' recent dictum that it should be eliminated from the operative methods. It is so simple, so effective, and so free from danger should pregnancy supervene that it seems worthy of continued use. The third group of operations has almost an infinity of modifications according to the predilections of the operator, and within the limits of a short article it is impossible even to enumerate them. A reflection born of experience is, that before using the round ligaments to keep the uterus in position, it were well to investigate the condition of those ligaments in the particular case. It is no uncommon experience to find such thin, ill-developed ligaments that to trust to them for maintaining a proper uterine position would be unwarrantable optimism. A second may be added—namely, that care should be taken to avoid strangulating the round ligament during the operation, as persistent pain has often been noticed over the area where the ligament has been drawn through the fascia.

My personal experiences of the after-results of both direct fixation and of various methods of shortening the round ligaments have been uniformly good, but of the two there have been fewer complications after the plain fixation.

Simple Prolapse of the Uterus.

The treatment of this condition when causing symptoms resolves itself into either supporting the uterus by some form of pessary, or devising such reparative operative procedures as will permanently maintain the uterus in its proper position. It is a growing conviction of the writer that the symptoms of prolapse are less dependent upon the actual position of the uterus than they are upon the concomitant prolapse of the vaginal walls. Early stages of prolapse may undoubtedly be cured by careful attention soon after childbirth by the insertion for a few months of a suitable pessary and by the institution of regular muscular exercises, not the least important being those which have for their object the re-education of the vaginal muscles themselves. In more advanced cases the question arises as to whether the condition is to be palliated or cured. Comfort can be secured by pessaries, but at the cost of several minor troubles and with the need of constant supervision. In some cases the general health, age, or considered choice of the patient may preclude any other method of treatment, or she may be at a time of life where repeated pregnancies are to be

anticipated. In any of these instances the palliative treatment must be considered, but, in general, curative treatment by operation is the method of choice. In any given case the operation must be most carefully considered and so planned in its scope and details as to restore the cervix and vaginal walls as nearly as possible to their original condition. The orthopaedic rule that it is wise to over-correct a deformity is equally true in carrying out operations for the cure of prolapse. In a simple case of prolapse it is hardly ever necessary to open the abdomen, while, however advanced the condition is, the uterus should on no account be removed unless there be some other condition making the course imperative.

In patients past the menopause, with marked cystocele and prolapse, the operation of interposing the uterus between the bladder and the vaginal wall has a certain though limited usefulness. My own experiences of it have been uniformly good. Lastly, in appropriate cases Le Fort's operation (uniting anterior and posterior vaginal walls along the middle line) is easy of accomplishment and gives very good results.

Prolapse Associated with Retroversion.

Prolapse associated with retroversion is commoner than simple prolapse. The treatment follows closely the lines indicated for the last-named condition but with this important difference, that a constant aim in the operative technique should be to leave the uterus in the normal position of anteversion. This position may be obtained during the vaginal procedures, but should it be found on the completion of these manipulations that the uterus is still retroverted or flexed, the abdomen should be opened and a ventral fixation done. The round ligaments are not to be relied upon in the operative treatment of prolapse with retroversion.

J. BRIGHT BANISTER, M.D. Camb., M.R.C.P. Lond.,
F.R.C.S. Edin.,

Consulting Obstetric Surgeon, Queen Charlotte's
Lying-in Hospital; Assistant Obstetric
Physician, Charing Cross Hospital.

THE BATEMAN APPEAL.

As already explained in THE LANCET, it has been felt that material assistance ought to be offered to Dr. Bateman to meet the legal expenses of his recent successful appeal against conviction and to make good the deficiency in his professional income. Accordingly, the Bateman Fund has been opened and a list of contributions appeared in the last issue. We have received additional contributions as follows:—

	£	s.	d.
Amount already received and acknowledged	314	10	6
Dr. L. G. Glover	5	5	0
Lancashire and General Ass., Co., Ltd. ..	5	5	0
Dr. W. C. Humphreys	5	0	0
Dr. Miles H. Phillips	3	3	0
Mrs. M. M. Brewer	2	2	0
Anonymous	1	1	0
Mr. Harold Barwell	1	1	0
F. J. B.	1	1	0
Mr. J. H. Brannigan	1	1	0
Dr. J. Charles	1	1	0
Dr. Arthur Crook	1	1	0
Dr. C. H. Dodd	1	1	0
Dr. Chas. J. Girling	1	1	0
Dr. Geo. Morgan	1	1	0
Dr. V. Tighe	1	1	0
Dr. Leslie B. C. Trotter	1	1	0
Mr. H. B. Walker	1	1	0
Dr. Waller	1	0	0
Dr. S. A. Lane	1	0	0
Dr. James Melvin	1	0	0
Trained Nurse	1	0	0
Dr. John Murray	10	6	
Dr. R. W. Payne	10	6	
Dr. John Armitage	10	0	
Dr. Arthur Burton	5	0	

Remittances should be forwarded to the Manager of THE LANCET, 423, Strand, W.C.2, and made payable to the "Bateman Fund Account."

Special Articles.

TREATMENT OF WAR INJURIES AT SPECIAL SURGICAL CLINICS.

BY CHARLES MACKAY, M.D., B.S. MELB.,
LATE LIEUT.-COLONEL, R.A.M.C.; MEDICAL OFFICER IN CHARGE
ORTHOPÆDIC CLINICS, MINISTRY OF PENSIONS;

AND

D. DENHAM PINNOCK, F.R.C.S. ENG.,
ASSISTANT SURGEON, TEMPERANCE HOSPITAL; MEDICAL
OFFICER IN CHARGE ORTHOPÆDIC CLINICS,
MINISTRY OF PENSIONS.

AMONG the many forms of disability which were incurred by all ranks through service in the late war, of which the disabling effects continued in a more or less high degree after leaving the Service, a larger proportion falls within the purview of the surgeon rather than of the physician. The number of such cases was so great that the Ministry of Pensions found it necessary to make special arrangements for dealing with them. The establishment of Special Surgical Clinics was an important part of these arrangements.

A Special Surgical Clinic is in essentials an out-patient orthopædic treatment centre. It consists of treatment rooms, surgeon's examination room, waiting room for patients, and suitable accommodation for massage staff. In establishing Special Surgical Clinics every endeavour was made to utilise the facilities at existing civil institutions, these facilities being in many instances expanded to meet the special need. Even with this expansion, however, the civil hospital facilities fell short of requirements, and further facilities were rendered available through the agency of the British Red Cross Society, who acquired suitable premises and opened clinics under the administration of a commandant. Over and above these, the Ministry itself established a number of clinics staffed and administered by the department.

These Surgical Clinics have two main functions: (1) The examination of pensioners suffering from war injury for the purpose of determining the need for treatment, surgical appliances, &c.; and (2) the provision of such treatment as can suitably be undertaken at the clinic.

In the general scheme of the Ministry for dealing with surgical cases, the Special Surgical Clinics are linked up with the surgical hospitals, and with the centres for the provision of surgical appliances and artificial limbs. They may refer cases to hospitals for in-patient treatment, or to the Appliances and Limb Centres to be provided with appliances or limbs. They may have referred to them cases from hospital for the purpose of carrying on or supplementing the surgical work which has been done while the man was an in-patient. They may have cases referred to them from the Appliances or Limb Centres, for an opinion as to the man's precise needs, or for a report as to whether an appliance or limb already provided is entirely suitable. In addition to these sources of supply, many cases are referred to the clinics from the various local offices set up by the Ministry throughout the country for the performance of the local work of the department. When a man is referred to the clinic, there is sent at the same time a dossier containing documents summarising the man's medical history as known to the Ministry. This history consists of medical notes made at the time of previous examinations by medical boards and other medical officers. In addition, it includes the records as to the results of any previous courses of treatment. At the outset, therefore, the surgeon at the clinic, is not dependent for his knowledge of the case upon what he himself can ascertain by the present examination. Where the man is provided with treatment at the clinic, the surgeon, on the man's discharge from treatment, continues the history

records by adding his own notes, and incorporating the case-sheet and any pathological reports or X ray films, &c., in the treatment dossier, for the information of medical officers who may have to deal with the case in future.

Before proceeding to describe the more professional aspect of the work at these clinics it may be remarked, in illustration of the encouragement to pensioners to avail themselves of such treatment as may be considered to be necessary, that the pensioner's travelling expenses between his home and the clinic are paid by the Ministry, whether in respect of a single attendance for the purpose of medical examination, or the more frequent attendances which are involved in a course of treatment. In addition, if the man's attendance will necessitate his absents himself from work on one or more occasions during the week, he is paid an allowance in respect of loss of remunerative time. Further, if the circumstances of his course of treatment are such as to necessitate his absents himself from work entirely, either because of the frequency of his attendances or because it is an essential part of his treatment that he should not work, he is granted, in lieu of any pension which he may be drawing, an allowance in respect of himself at a rate equivalent to pension for total disablement, together with allowances at corresponding rates in respect of his wife and children. No pensioner need therefore be deterred from accepting a course of treatment on account of financial considerations, and pensioners are consequently much more favourably placed in this connexion than is the average civilian.

Types of Case Treated.

The treatment provided at a clinic is necessarily somewhat limited in scope, but is of considerable variety. Such remedial agents as surgical dressings, massage, electricity, heat, passive and active movements, Swedish exercises of remedial character, and exercises for muscle re-education are extensively employed. The types of case in which clinic treatment is undertaken fall into the following classes:—

- (1) *Nerve Injuries*.—Mainly those cases which have had nerve suture performed at a comparatively recent date, or other nerve injuries which are slowly recovering, and require treatment by massage, electricity, and muscle re-education.
- (2) *Old Joint Injuries* with varying degrees of limitation of movement.
- (3) *Extensive Wound Scarrings* with considerable muscle weakness and wasting of limbs.
- (4) *Old Bone Injuries* with recent or old sinuses requiring dressing and supervision, also recent bone grafts.
- (5) *Organic Injuries* of various kinds, with functional paralysis of varying degree super-added, and requiring both physical and psychical re-education.
- (6) *Amputation Stumps* requiring dressings or treatment for pain, &c.
- (7) Various forms of arthritis.

The cases which have responded best to treatment are the severe wounds with extensive scarring, much muscle weakness, wasting of limbs, and joint stiffness. Under treatment with varying applications of massage, heat, faradic electricity, graduated exercises, much has been done to restore these limbs to a high degree of usefulness. Partial injuries to nerves and tendon transplantations for drop-wrist have also been very successfully dealt with. On the whole, it has been somewhat disappointing to see the final results of many nerve suture operations, especially those on the sciatic nerve, external popliteal nerve, and median and ulnar nerves. After months and years of continuous treatment some of these cases show little response in the direction of increased movement or power in the foot and hand, the foot remaining partially inverted and dropped in spite of treatment. Although disappointing from the point of view of return of movement, nerve suture with after-treatment has probably been of very definite physiological value to the limb, in preserving a better blood-supply with less liability to trophic disturbances. The most encouraging of these nerve cases have been those of musculo-spiral suture, and this experience has been common to many observers. In the case of the lower

limbs, operations on the knee-joint have necessitated a large amount of after-treatment. Where the injury for which the operation has been done has occurred several years before, the wasting of the thigh, especially of the vastus internus muscle, requires much treatment to bring it up to anything approaching normal. Injuries of the shoulder, either of the joint itself or in the neighbourhood of joint, are the cause of severe disablement. Very often the pensioner comes to the clinic unable to abduct and to elevate his arm as far as a right angle. Much improvement may be effected in these cases by treating patients in the lying-down position. By this means the weight of the arm is taken off the weakened muscles, and after the application of massage and heat the pensioner is often able to raise his arm much further in this position than he had previously thought possible. Carefully graduated exercise in the lying-down position is essential for the recovery of movement at the shoulder. By means of pillows the patient can be gradually raised to a sitting-up position, and movements which were at first impossible become comparatively simple and easy. To begin the attempt to obtain movement in the region of a damaged shoulder-joint in the standing or sitting-up position is to invite pain and consequent reluctance to attempt movement on the part of the pensioner. In the lying-down position his confidence is easily obtained, and he adjusts his movements to his own feelings. No attempt is made to force the arm above the position at which he feels pain. The cardinal idea is that the movements should be voluntary and supervised. It is well to remember that an arm and hand are useless unless the thumb can be opposed to the fingers. This is the supremely essential movement to be striven for in the upper limb.

Function, no matter how obtained, whether by so-called trick movements or otherwise, is the aim of treatment at the clinics. With all forms of injury, it is recognised that movement is the ultimate goal, and that active movement should be encouraged by every means possible.

Re-education.

The old conception that the more one did for the patient the better, is gradually being improved into that of encouraging and supervising the patient to do as much as possible for himself. It is even yet very difficult to get masseuses to recognise that what the patient does for himself is of infinitely more value than what is done for him. The tendency to take up too great a proportion of the treatment time in applying massage and electricity requires to be counteracted by the surgeon. Muscle re-education, in the sense of getting the pensioner to concentrate his attention on his own supervised attempt to recover power in weak or partially paralysed muscles, always working to this end with the aid of gravity, and in the positions where the muscles can work at the best advantage, is regarded as the most important part of the modern treatment of these conditions, and is extensively used at the clinics. It may be remarked that experience at these clinics lends strong confirmation to the opinion that in all forms of physical treatment a certain amount of psychical treatment is also necessary. It has not always been easy to get the individual pensioner into a frame of mind where he is inclined voluntarily to assist with his own treatment. The tendency to do little for himself can only be counteracted by the surgeon in charge taking a personal interest in the individual, and showing him how much to his own future advantage it is to assist in his own treatment. The atmosphere thus created is a great help to the individual and to the clinic generally. Re-education in walking has formed an important part of the advanced treatment of many cases of severe injury of the lower limbs. As an essential part of treatment the provision of various types of orthopaedic appliance should be mentioned, as well as that of surgical boots and shoes.

Apart from purely surgical cases there are also treated at these clinics many medical conditions, such

as rheumatism, myalgia, sciatica, and various forms of arthritis. These are treated by means of heat, massage, ionisation, and so forth. The chronic cases of arthritis are necessarily the most obstinate in responding to treatment, and it is often very difficult to decide when treatment should be discontinued, especially in the elderly pensioner. In many instances all that can be done is to attempt to relieve severe pain, and as pain is a purely subjective phenomenon, the question as to whether any definite improvement in the condition can be accomplished by treatment requires very careful investigation and consideration.

In conclusion, we beg to express our indebtedness to the Director-General of Medical Services of the Ministry of Pensions for his kind permission to publish this article.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

(Continued from p. 509.)

THE APPROVED SOCIETIES AND THE MONEY BENEFITS.

The Controller's Evidence.

(App. A. 56.) The ordinary benefits of the National Health Insurance Act are four in number—namely, medical benefit, sickness benefit, disablement benefit, and maternity benefit. The official evidence in regard to medical benefit has been summarised. So far as this benefit is concerned, the only duty devolving upon Approved Societies is that of keeping the Insurance Committees informed of the persons who are entitled to medical benefit, and of those who cease to be so entitled. For all but a relatively small part of the insured population the other three benefits (collectively known as the money or cash benefits) are administered by Approved Societies.

Rates of Sickness Benefit.

(App. A. 57-8.) Sickness benefit consists of money payments made after the third day of incapacity, at the following rates: (a) After 104 weeks in insurance and payment of 104 weekly contributions: for men, 15s.; for women, 12s. (b) After 26 weeks in insurance and the payment of 26 weekly contributions, but before completion of the conditions indicated at (a): for men, 9s.; for women, 7s. 6d. Disablement benefit is a continuation of sickness benefit after 26 weeks of payment have been made and is at the rate of 7s. 6d. a week for both men and women.

Conditions Attaching to these Benefits.

(App. A. 60-3.) In general, claims to sickness and disablement benefits are based upon the medical certificates required to be furnished by the insurance practitioners. The member must send notice of incapacity within three days if he wishes to avoid some loss of benefit. The onus of giving notice of illness is placed upon the member himself, and there is nothing in the Acts to suggest that this duty devolves upon relatives or friends of the member, or upon the medical attendant, even in cases where the member is obviously incapable of attending to the matter himself—e.g., in cases of mental derangement. Mere ignorance of the requirements of the Acts or of the society's rules regarding the prompt notification of illness is not accepted by societies as a sufficient ground in itself for delay in giving notice

* In previous articles the proceedings of the Commission were reported under the following headings: Introductory Note; The Scope of the Insurance Scheme (see THE LANCET, Jan. 31st, pp. 247-8); The Provision of Medical Benefit (Feb. 7th, pp. 301-3; Feb. 14th, pp. 355-6; Feb. 21st, pp. 403-5); Financial Provisions of the Act (Feb. 28th, pp. 454-7); Medical Certification and the Regional Medical Staff (March 7th, pp. 508-9).

References to the official statement which has been issued as an appendix in four sections are given thus: Section A, para. 69, is shown as "App. A. 69," and references to the oral evidence thus—Q. 1369.

of illness. In practice, however, societies are prepared to give relief from the usual consequences of late notification of incapacity in cases where they are satisfied that substantial grounds can be shown for the member's delay.

(App. A. 64.) Cases in which sickness or disablement benefit is claimed on the ground of pregnancy occasion a considerable amount of difficulty to societies on the ground that the performance of full household duties may not unreasonably be regarded as an alternative occupation in the case of a married woman. Where, however, the claim is not made until a comparatively late stage, it would be much more likely to receive favourable consideration inasmuch as societies in general are prepared to recognise the inherent probability of incapacity during the weeks immediately before confinement.

Supervision of Claims.

(App. A. 68.) All societies are required to include in their rules a provision in the form prescribed by the Ministry regarding the behaviour of members during sickness—e.g., the patient must obey the instructions of his doctor, must not be absent from home between certain stated hours, and must not go away without the society's consent.

In general, the arrangements made by societies for supervision are of two kinds—namely: (1) Sick visitation. (2) The reference of the member for examination by a Regional Medical Officer or some other independent doctor in any case where the continuance of incapacity is thought to be in doubt. The work of the sick visitor is in no way concerned with the medical treatment of members who are incapable of work, but he has to see that the rules as to behaviour during sickness are observed and he may bring to notice circumstances which would seem to raise doubt as to the continuance of incapacity.

(Q. 313-4.) As the change from what is called sickness benefit to what is called disablement benefit may appear to open up the possibility of a long period of payments, a number of societies are inclined to referee automatically every case when 26 weeks benefit has been paid. The Department, said the Controller, object to this.

Maternity Benefit.

(App. A. 74-6.) Maternity benefit consists of a payment of 40s. on the confinement of the wife (or where the child is a posthumous child, of the widow) of an insured man, or on the confinement of an insured woman; where the woman is married and is herself insured, two payments of this amount are made. This benefit is in all cases required to be applied in the interest of the mother and child and may be administered, in the discretion of the society, either in cash or in kind. A few societies, instead of paying over the full amount of the benefit to the woman in cash, make provision for her confinement either by providing the services of a doctor or midwife or by arranging for her admission to a maternity home. In general, however, the benefit is administered as a payment in cash. The Controller was asked—

(Q. 354.) Have you any indication of the extent to which the maternity benefit is entirely absorbed by the doctor's fees?—Yes. I think the increasing tendency is that the doctor endeavours to get the whole amount of the maternity benefit. When originally 30s. was paid as maternity benefit the doctor took 30s. as his fee. Now that we pay 40s. his fee very frequently is 40s.

Arrears and Disputes.

(App. A. 103-4.) Contributions are not payable during weeks of notified sickness, and a member is also allowed four weeks of unemployment in a year without falling into arrear. Beyond this point the rates of sickness and disablement benefits are reduced in accordance with a sliding scale until they reach a point (under 26 contributions) where all benefits are suspended. Reduction of rate or suspension can be avoided by the payment of arrears penalties.

(App. A. 111.) As to disputes in regard to a claim to benefit, societies are required to make due provision in their rules. There is no prescribed form of procedure for the determination of disputes between societies and their members; there is in fact much divergence of practice among societies in this respect. A considerable majority of societies have, however, adopted the Department's model rules. After a dispute has passed through the procedure laid down in the society's rules, either party to a dispute may apply to the Minister of Health for leave to appeal.

(Q. 454.) Are you satisfied that the present arrangements afford sufficient protection to an insured person who thinks he has been unfairly treated?—On the whole the arrangements work fairly well. . . . We still have difficulties. The rules of some societies are still too cumbrous; insured persons do not understand them. In some societies insured persons have to appear before two, and possibly three, separate tribunals before their case is finally disposed of. In a few cases societies still continue to charge what we regard as rather onerous deposits payable by the insured person as a condition precedent to his appeal being heard, and I am inclined to think that in certain societies insured persons, when their benefit claim is refused, are not informed of their rights and of the procedure which they ought to follow as fully as they should be.

The Controller indicated that in this matter the powers of the Department appeared to be inadequate.

(To be continued.)

MEDICINE AND THE LAW.

CASE DECIDED ON MEDICAL EVIDENCE.

AT a recent inquest at Hungerton in Leicestershire it was proved that the vicar, the Rev. W. G. C. Bettison, had shot himself with a gun when suffering from the effect of mental depression, blowing away his cheek and part of his upper jaw. His sister had gone to him after an interval, as was proved by witnesses, and while she was alone in the room with him a shot had been heard which she afterwards declared that she had fired at his request to put him out of his pain. Owing to her mental state she had to be removed at once to a mental hospital. The grave question therefore arose as to whether the sister had been guilty of murder or whether the deceased had committed suicide. As to this Dr. E. Williams gave evidence to the effect that the wound in the head described above must have proved fatal within an hour, and had, without doubt, been self-inflicted. The second wound had blown away half of the heart and the left lung. It was questionable whether Miss Bettison could have known whether her brother was dead or alive when the second shot was fired. He did not think it possible that Mr. Bettison could have said anything coherent after the first wound had been inflicted, although he might have made a noise. This had reference to Miss Bettison's statement that her brother had asked her to kill him, with reference to which evidence had been given by a person who had been in the passage outside the room that he had heard no conversation. It had also been shown that time had elapsed between the first and second shot, during which Miss Bettison had been summoning assistance. Dr. Williams was of opinion that, owing to her mental condition, Miss Bettison might easily have imagined that she had been asked to fire the second shot. The coroner, in addressing the jury, pointed out that no one was justified in putting an end to the life of another to save him from suffering, but added that owing to the medical evidence this question did not arise. He invited the jury accordingly to return a verdict of suicide while of unsound mind, and this was done. In comment it is to be observed that the verdict was right according to the evidence. No jury at an assize would have found Miss Bettison guilty of murder without proof that her brother was alive when she fired the second shot, as probably she did, particularly as her statement that she had been asked to fire it, made in the condition in which she was, was negatived by the conditions due to the wound inflicted on himself by the deceased.

ACTION FOR ALLEGED NEGLIGENCE IN ADMINISTERING AN ANÆSTHETIC.

In the case of *Murdock v. Holmes and Taylor*, recently tried at Leicester Assizes, damages were claimed by the plaintiff for the loss of the sight of one eye, on the ground that this had been caused by the negligent administration of an anæsthetic during a prolonged operation. The case for the defence was that the injury to the eye, if caused by the anæsthetic, was not due to any negligence in administering it, but to septic conditions in the plaintiff at the time when it was administered. This case presented some problems interesting particularly to anæsthetists and ophthalmologists. The medical facts appear to have been briefly these. A laparotomy was performed to find and remove the cause of an obstruction of the bowels from which the patient had obviously been suffering for some days. An anæsthetic, consisting of two parts of ether to one of chloroform, was administered on an open mask, a Gamgee pad being placed on the face. It appeared in the evidence that twice this pad had become so wet with the anæsthetic that the anæsthetist changed it. On the day after operation the patient complained of violent pain in the left eye and he was seen soon after by an ophthalmic surgeon, who found a condition of the eye "not inconsistent with some anæsthetic having got into it." There was swelling of the corneal epithelium, but no abrasion, and the eye was acutely inflamed. Eventually a dense scar formed across the middle of the cornea. The defence rested on the fact that the patient's state was highly toxic, the bowels were opened only with great difficulty during the days after the operation, and that a damage so slight as to be easily recovered from in the normal subject led in this poisoned subject to the serious keratitis resulting in scar. It was admitted by some of the experts giving evidence for the defence that this damage was probably caused by drops of liquid anæsthetic, but others maintained that the vapour itself would have been enough, in the patient's condition, to set up the corneal damage. This appears an interesting and important point, for no care, however meticulous, can prevent anæsthetic vapour reaching the eye. There is, we believe, no evidence, clinical or experimental, to support the contention that in an unhealthy subject the normal engorgement caused by inhalation of the anæsthetic could have caused the lesion. There is, however, good evidence to show that even considerable amounts of the anæsthetic employed can be dropped into a normal eye and lead to no serious consequences.

The jury after a prolonged hearing were unable to agree as to a verdict and were accordingly discharged.

DYSON v. MEYRICK: JUDGMENT.

The Lord Chief Justice gave judgment for Dr. Meyrick on his claim for the sum of £98 4s. 6d. (the sum to which the original sum sued for had been reduced by the finding of the jury as to the agreement for weekly payments) and allowed him the "appropriate costs." He gave judgment for Mr. Dyson on the counterclaim for 20s., with the costs of the counterclaim.

In delivering judgment Lord Hewart said that the finding of the jury that Herber. Dyson was confined in a locked room at times was an exceedingly grave matter, and as to it the evidence was overwhelming. It was impossible not to sympathise with the patient as well as with those having care of him, but it was tolerably obvious that the case was not one suitable for Dr. Meyrick's house, hence, perhaps, the seclusion and the concealment of it. On behalf of the defendant it had been contended that this breach of duty went to the root of the whole matter, and constituted a defence to the entire claim. For some reason or other, however, the jury had found that the only damages suffered by Mr. Dyson through the seclusion of his son were to be assessed at 20s. Whatever his Lordship's own opinion might be about the matter, it was his duty loyally to observe the verdict of the jury, and for that reason he was unable to say that Dr. Meyrick's breach of duty could be said to go to

the root of the contract, although he was clearly of opinion that it invited the attention of the Board of Control. In the circumstances he gave judgment to the effect above stated.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The "Haff Disease."

Prof. Lentz, of the German Health Office, recently read a paper before the Berlin Medical Society on the causes of the peculiar disease among fishermen of the Kurisches Haff, a bay in Eastern Prussia, which was described in one of my previous letters (see THE LANCET, 1924, ii., 774). He said that the disease had spread since last autumn, so that the number of cases now totalled 600, with three deaths. As regards symptoms, the pains in the muscles had sometimes been so severe that the fishermen were unable to steer their boats. The urine was scanty and contained much albumin and granulated casts, which were sometimes present after three weeks. Many of the fishermen became ill on successive occasions, several of them up to six times, when they put to sea on the bay. At the post-mortem examination of a fisherman marked parenchymatous degeneration of the kidneys was found. Prof. Lentz was successful in ascertaining the cause of the disease. To find out whether it was caused by an infection one of his assistants injected into himself a quantity of blood of a man who had just become ill. The assistant showed no symptoms. But 1 c.cm. of the water of the bay injected into a fisherman who had already had the disease produced a fresh attack with typical symptoms. It could thus be concluded that the agent of the disease was contained in the water. Further investigations proved that the water from the cellulose factories by which the water of the bay was contaminated contained 28 mg. of arsenic to the litre, and in the blood, urine, and various organs of men and animals who died from the disease arsenic was found. The poison in the water is taken up by the algæ of the bay and thus developed into arseniuretted hydrogen, which is inhaled by the fishermen. The cellulose factories have been working for many years, and to account for the fact that their waste waters had not formerly developed a poisonous action two reasons are put forward: (1) that owing to the water of the river Nogat being dammed up, the water of the bay had been in a more stagnant condition than formerly; and (2) that the factories had since the outbreak of the war used Rio Tinto pyrites, which contain arsenic, instead of the Cyprus pyrites. The latter raw material is now in use again and the disease has disappeared. To assist the indigent fisher population the Government has set aside a large sum.

An Action for Damages.

Before the Berlin law courts a member of the medical staff of the municipal Friedrichshain Hospital brought an action against the city of Berlin for the payment of 600 marks (£30) monthly to defray the costs of a sojourn in a southern climate, rendered necessary through his having become incapacitated by tuberculosis during his hospital service. The plaintiff stated before the court that he had been in charge of the tuberculosis ward of the hospital in 1922 and 1923 and that the hygienic conditions then were very bad, and owing to the general poverty tuberculosis had so increased that the wards were overcrowded. The plaintiff stated that he had never been ill before he had been appointed to the tuberculosis ward, and that three other medical men and several of the nurses had also caught the disease there. The statements of the plaintiff were confirmed by witnesses. Counsel for the plaintiff alleged that although things had now become normal the hygienic state of the hospitals had been very bad for a time, as owing to the depreciation of the currency the city of Berlin had scarcely the necessary means to run the hospitals at all; further, that the plaintiff had

caught the germs of the disease during the war at the front; and that independently of its hygienic condition every tuberculosis ward was a danger to the medical and nursing staff who were compelled to live there. The court finally pronounced judgment in favour of the plaintiff, and ordered the city of Berlin authorities to pay the plaintiff £30 per month for six months during the latter's stay at the health resort.

Death of Prof. Julius Hirschberg.

The death is announced of the ophthalmologist Prof. Hirschberg, a doyen of the Berlin medical profession, at the advanced age of 82 years. When assistant to the great ophthalmologist Prof. von Gräfe of Berlin, Hirschberg carried out research work on cancer of the retina and later extended his work widely in his own specialty. He was the first to recommend the use of the electro-magnet for the extraction of iron splinters from the eye (1885). His work "Introduction to Ophthalmology," published in 1892, was translated into several languages. He was not only a distinguished ophthalmologist, but a distinguished philologist and historian as well. He published an historical work in several volumes on the ancient Greek, Roman, and Arabian ophthalmologists. Apart from these more professional studies, he wrote essays on Homer and Aristophanes. All his life Hirschberg was one of the most energetic members of the Berlin Medical Society, and even in his latter years, notwithstanding his age, he was seldom absent from a meeting. He bequeathed his well-known library to the State.

Conviction of a Christian Scientist.

In the city of Lübeck recently a boy received a severe abdominal wound with prolapse of the intestine through falling on a paling. Although his suffering was great no medical man was consulted at the time of the accident, but the parents approached a Christian Scientist, who, it was alleged, had successfully cured a fistula in a relative of the family some time previously. The "scientist," a woman, first refused to deal with the case because the parents did not belong to the sect, but finally came to the house of the patient and prayed with the family. She declined to see the wound, because she said that would prejudice the effect of the prayer. The boy's condition grew steadily worse, with the result that the parents after two days conveyed him to a hospital. He was then operated on, but could not be saved as severe peritonitis had already developed. The "scientist" was then prosecuted for manslaughter through neglect. Witnesses for the defence gave evidence that they had in numerous instances seen grave diseases cured by Christian Science. A medical witness for the prosecution stated that in the above case an operation performed within six hours after the injury would very likely have saved the life of the boy. The jury gave a verdict of "Guilty," and the defendant was sentenced to one year's imprisonment.

Statistics of German Students.

The number of students in the German universities has decreased steadily during the last three years; for the years 1922, 1923, and 1924 respectively, 12,296, 10,290, and 7728 students matriculated. The reason of this diminution is that through depreciation of the currency the financial condition of those classes whence the majority of the students were formerly recruited—the liberal professions, Government officials, and the middle classes in general—could not bear the cost of study. Many of the students had to interrupt their studies and to enter into business, and even take to manual work, to earn a livelihood. Now that the currency has become stable again and the fees of study considerably reduced, the number of students has increased to 8313. But the number of medical students is only 1810, against 1967 last winter, women numbering 331 and 315 respectively. The repeated warnings against medical study because of the cheerless outlook in the medical profession has obviously produced these figures.

"Audi alteram partem."

THE BATEMAN APPEAL FUND.

To the Editor of THE LANCET.

SIR,—In enclosing a small contribution towards the Bateman Appeal Fund, may I add my surprise that during the trial no reference was made to a paper on post-partum avulsion of the uterus, with a case, followed by recovery, which is fully recorded by Mr. Hopkins Walters in the Transactions of the Obstetrical Society of 1884, p. 233. In the discussion that followed the late Dr. G. E. Herman said that "a great value of Mr. Hopkins Walters's paper was in this: that in any future case of the kind in which evidence on the subject might be required in a law court, those whose duty it was to form an opinion would find all available facts bearing on the subject brought together in Mr. Walters's paper."

I am, Sir, yours faithfully,
MILES H. PHILLIPS.

Sheffield, March 9th, 1925.

THE FUTURE OF MEDICINE IN INDIA.

To the Editor of THE LANCET.

SIR,—In an editorial article contained in your issue of Feb. 28th on this subject I am credited with giving a benediction to the Lee Commission's proposed R.A.M.C. (India). You correctly quote me as stating in *THE LANCET*, Sept. 20th, 1924: "... it may confidently be expected that a number of well-qualified young men of the home medical schools desiring an Indian career will join this service with a view to obtaining professional work in the provinces, and when political opinion has settled down they will have a full and useful career." But I would like to state that this was written under the impression that the strength of the War Reserve, transferred from military to the civil side, would remain approximately the same as it was before the war. My idea was that the proposed change would simply mean a resurrection of the I.M.S. under another name, and that the traditions of that service would be carried on uninterruptedly in the R.A.M.C. (India). I had overlooked the footnote on p. 12 of the Lee Commission's Report which runs: "On this point (War Reserve transferred to civil) we have proceeded upon the assumption that the quota of military medical officers from civil employ required for the Reserve will not exceed the total (122) specified in the D.M.S.'s memorandum of 2nd July, 1922, attached to Government of India Despatch No. 1 of 1923." This very seriously reduces the chances of officers joining the R.A.M.C. (India) obtaining civil employment.

The real attractions of the I.M.S. have always been that its officers held H.M. Commission, had opportunities for field service, and the prospects of work on the civil side. The combined strength of the R.A.M.C. and I.M.S. before the war was well over 1000. The proposed R.A.M.C. (India) would have to provide medical officers for both the British and troops, the curtailed War Reserve, political and other branches. Assuming that its strength would be 800, acceptance of the Lee Commission's proposals would mean that only 15.25 per cent. could hope for civil employment—that is, about 1 in 7, and of these a certain (unknown) proportion would be Indians.

In the real circumstances I do not think that the proposed R.A.M.C. (India) would be popular with the best young men of the home medical schools. At least six-sevenths of them would spend all their service in military employ, and men wishing for a military medical career would certainly prefer joining that splendid service, the R.A.M.C. I am also disposed to consider that the majority of senior I.M.S. officers would discourage young men at home competing for the R.A.M.C. (India). I doubt if the

proposed provincial medical service will attract any candidates. As one predicted, a certain number of men will doubtless seek employment under special contract; time alone will indicate how far these appointments fill satisfactorily the positions previously held by I.M.S. officers, and whether these contract men will be happy in their work.

I am, Sir, yours faithfully,

P. HEHIR,
Major-General, I.M.S. (ret.)

Westward Ho! Feb. 28th, 1925.

PRESERVATIVES IN FOOD: DRAFT REGULATIONS, 1925.

To the Editor of THE LANCET.

SIR,—These Regulations are certainly to be commended, and carry out largely the recommendations of the Departmental Committee, but in one respect they seem to be retrograde (I take it through some inadvertence)—that is, food sold in hotels, restaurants, &c. (see Part 2, Section 4, subsection (2), last sentence)—“provided that this provision shall not apply where the article of food is sold in any hotel, restaurant or other such place for consumption on the premises.”

At the present time the sale of preserved cream if sold for consumption on the premises requires a notice to be placed in a conspicuous position in the room, or a statement on the bill of fare or some other adequate means of similar intimation. (See “Milk and Cream Regulations, 1912,” Section V.) These Regulations are, however, to be revoked by Section 15 of the proposed new Order. The result is that any food, including cream, may have excessive preservative added.

Considering the large number of persons whose work necessitates their taking their meals in restaurants, it would appear that the proposed regulations still need some further modification for the protection of the public who use restaurants in order to prevent excessive quantities of preservative being added to food. Surely if it is desired to make some special provision in the case of restaurants, for example, as regards colouring matter or even preservatives, some limitations should be enacted, and not merely exemption of such premises.

A pleasing feature of the Regulations is that power is now sought (see Section V. (2)) to get over a difficulty to which I drew attention in 1922, when we found colouring matter being openly sold at the Dairy Show recommended for addition to milk, although the sale of milk with it or any preservative is illegal.

I am, Sir, yours faithfully,

G. CLARK TROTTER, M.D.,
Medical Officer of Health, Islington.

London, N., March 9th, 1925.

THE ACIDIC VALUE OF THE URINE IN SKIN AND OTHER MANIFESTATIONS.

To the Editor of THE LANCET.

SIR,—In his letter to THE LANCET of Feb. 28th Dr. A. Whitfield has written: “Dr. Semon, since the publication of the paper in which he was associated with Dr. Barber, has published another recommending X rays for acne, a disease which I am sure Dr. Barber will agree with me in regarding as lying on a foundation of seborrhoea; so that apparently Dr. Semon has not found the alkaline treatment alone sufficient. . . .” The implication would seem to be that I had used alkalis by the mouth in the treatment of acne, and found it of little or no effect.

May I be allowed to assure Dr. Whitfield that I have never prescribed bicarbonate of soda or any other alkali for that condition? My opinion of the value of “alkalisation” in acute seborrhoeic conditions, such as Dr. Barber and I had to treat at a base hospital in France, remains unshaken by my civilian experi-

ences since the war. There is, after all, nothing very novel in our conceptions. It has been long known that all inflamed mucous membranes are soothed by the oral administration of solutions of the alkaline salts, and, long before salicylates were introduced, that treatment was accepted and practised for the synovitis of rheumatic fever. If these structures are thus influenced, then why not the acutely catarrhal skin? In chronic cases of seborrhoeic type I have been less successful, and my results have seemed to vary inversely with the chronicity of the affection treated. In agreement with Dr. Barber I believe that the secondary infections with common organisms such as the staphylococci and the acne bacillus, which, as Dr. Whitfield maintains, will flourish on a seborrhoeic terrain, produce a local alteration, a sensitisation (to use a modern term), which is not so easily influenced by alkalisation as are the acute manifestations. It seems to me significant that it is just in this type that applications of tar ointments, &c., and X rays, are so valuable an adjunct to the general measures. It may be, on the other hand, as Dr. Doble claims, that “too much alkali (with a pH value of the urine as low as 7.2 to 8) will, as in his Case 1, cause the lesions to reappear.” I may therefore have overdosed my chronic and less-alkali-tolerant cases, none of which were submitted to the careful tests recorded in Dr. Doble’s paper; for, like Dr. Whitfield, I have hitherto employed only litmus as the reaction indicator.

The solution of the problem and the explanation of the failures seem to me a matter for prolonged biochemical investigation, in which a clinician like myself can play only a subsidiary part.

I am, Sir, yours faithfully,

HENRY C. SEMON.

Queen Anne-street, W., March 7th, 1925.

THE EFFECTS OF AN ANTISERUM UPON CANCER CELLS IN VITRO.

To the Editor of THE LANCET.

SIR,—I have read with great interest the observations by Dr. Thomas Lumsden under the above title published in THE LANCET of Feb. 21st. He concludes that antibodies more or less specific to cancer can be produced by its repeated inoculation into an animal of another species. That is, in his experiments, in vitro cultures of mouse tumour do not survive in the serum of rats and rabbits repeatedly inoculated with mouse tumour.

There is, however, another aspect. In 1912, the late Dr. G. Carrington Purvis¹ (Grahamstown) suggested treatment in cancer by injections of serum obtained from sheep after several inoculations with prepared human cancerous tissue. His object was to prepare “a cytolytic serum or a serum which would kill the cells of cancer occurring in a human being.” I examined some of the serum which he gave me, and I inoculated rats with mouse tumour, as well as the rabbit, sheep, and goat repeatedly with fresh human cancer tissue, and with cancer serum. The results obtained were given in a paper entitled *Some Reactions of the Blood After Cancer Inoculation*, read at the Seventeenth International Congress of Medicine (Therapeutics; Sub-Sect. Chem. Pathol.), London, 1913. In all cases the reactions of the blood were found to run parallel with reactions I had previously obtained with anti-iphtheritic serum and other immune sera. In August, 1924, I repeated the experiments in the sheep, in the Brown Institution, with results which fully confirmed the earlier ones. In no case did the grafts grow. A direct cytolytic effect on the serum in vitro was not investigated, as at the time the stimulation of protective substances or enzyme activity in vivo was aimed at. The clinical side from this point of view has still to be investigated. In only three cases has the serum been employed—

¹ Proc. Scottish Med. Soc., 1912, vol. vi., p. 43.

two by Purvis and one by myself. The condition of the patients, however, was too advanced for any definite conclusion. There is one point which needs consideration. The response to produce an effect was found to vary in the different animals. The sheep was more responsive than the rat, rabbit, and goat. The question arises whether the horse might be more suitable.

I am, Sir, yours faithfully,

J. A. SHAW-MACKENZIE, M.D. Lond.

DISLOCATION OF THE SEMILUNAR BONE

To the Editor of THE LANCET.

SIR,—MR. C. Noon's article on this subject in THE LANCET of Feb. 28th stimulates me to record a similar case which came under my care in the Northampton General Hospital last July. The patient was a man aged 28. He stated that while starting a car the handle became locked with the shaft and threw him over. He was referred to me by the house surgeon a few days after the accident. He was suffering from very severe pain in wrist and hand and was unable to move the fingers. There was general swelling of the wrist. An X ray plate which had been taken from the dorsal aspect showed nothing beyond a slight irregularity of the proximal row of carpal bones. A lateral view of the joint was obtained and this showed forward dislocation of the semilunar bone with rotation of the inferior articular surface to the palmar aspect. Manipulation under anaesthesia failing to reduce the dislocation, an open operation was performed one week after the accident. An incision was made just to the radial side of the tendon of the flexor carpi radialis, avoiding the median nerve, and the dislocation reduced without much difficulty. The wrist was put up on a splint in a slightly flexed position to prevent redislocation. He was encouraged to move his fingers from the first and no splint was used after a fortnight. An excellent functional result was obtained, but three months after the accident flexion and extension movements at the wrist joint were still somewhat limited.—I am, Sir, yours faithfully,

C. COLGATE HOLMAN.

Northampton, March 3rd, 1925.

BISMUTH THERAPY IN SYPHILIS.

To the Editor of THE LANCET.

SIR,—In the leading article upon this subject in THE LANCET of March 7th with reference to my review in the first number of *The British Journal of Venereal Diseases* you mention the omission from the bibliography of Levaditi and Nicolau's paper in the *Annales de l'Institut Pasteur*. The explanation is, that when the bibliography was compiled, it had to be kept within small compass on account of considerations of space. As it turned out, however, it might have been extended. The reference to Levaditi's Harben Lecture (*Journal of State Medicine*, 1924, xxxii., 62) was considered sufficient, and that it would be more easily accessible. In that lecture Levaditi explains the details of the bismoxyl experiments, and also gives a reference to his joint paper with Nicolau (*Compt. rend. Acad. des Sc.*, 1923, clxxvi., 1189). On account of the immense literature on bismuth therapy, a rather rigorous selection had to be made, otherwise the bibliography would have been of greater length than the review. I do not think, however, that anything essential was omitted.

In the next issue of the *B.J.V.D.* there will be found a brief résumé of the main experimental and clinical reasons which compel me to take a different view from Lomholt as to the therapeutic value of mercury.

I am, Sir, yours faithfully,

Manchester, March 7th, 1925.

E. T. BURKE.

THE FULL RESOUNDING LINE.*

To the Editor of THE LANCET.

SIR,—The day before I read, with the most sincere regret, of Sir Clifford Allbutt's death, I had occasion to seek out his Cavendish lecture from my archives. The passage I was in search of was in the middle of the pamphlet, but my eye fell upon the opening paragraphs, and I devoured them as if entranced by the magic of the wording. It is no wonder, I said to myself, that he was accounted a master of graceful and scholarly exposition. Lest your readers should have forgotten, as I had forgotten, the grace and charm with which this courtly old gentleman (and he was such a gentleman) was capable of investing the severest of subjects, I append the passage—"for Delight," as Bacon says of Studies, "for Ornament and for Ability."

"In a little tract of the brain, one so small that an infant might grasp it, lies the engine of all that makes life worth living; and but a few inches below it, where brain and spine unite, is a still smaller tract, where lies the knot of life itself. The upper tract has its times of energy and of repose, by sleep its ravelled sleeve is knitted up; but the knot of life itself knows no pause, no quiescence; let its vigilance be at fault for a few seconds, and the busy frame it governs will drop into silence. Save as a lesson in physiology, these are strange parts to us; yet there is another unsleeping minister of life, our familiar, of whose pulses Harvey was rapt into saying that they 'are of the spirit of the blood acting superiorly to the powers of the elements . . . and that the soul in this spirit and blood is identical with the essence of the stars.' When the pulses of this instrument beat in harmony we feel within us that all is well; when they are jangled and out of tune we are dismayed. Often when in the still night I hear, as I lie, the calm and continual rhythm of my familiar spirit ever winnowing boon from bane, I am lost in wonder at the long procession of these notes of human time, at this perpetual beat of the manifold tides of life. As I listen to its notes they seem to fall into the burden:—

'So schaff' ich am sausen den Webstuhl der Zeit,
Und wirke der Gottheit lebendiges Kleid.'

Sixty times a minute, at least; 3600 times an hour, 86,400 times a day, for us heedful and heedless, does this shuttle of life throb to and fro; for us in tireless periods this pendulum of man's gravitation tells the seconds which can never return."

I am, Sir, yours faithfully,

Harley House, N.W., Feb. 28th. LEONARD WILLIAMS.

* Pope's reference to Dryden in his *Imitations of Horace*:—
"The full resounding line,
The long majestic march, and energy divine."

HEXYL RESORCINOL.

To the Editor of THE LANCET.

SIR,—In your issue of Feb. 28th you refer to the new synthetic compound hexyl resorcinol which, when administered by the mouth, renders the urine highly bactericidal, and you refer also to the desirability of obtaining clinical evidence as to the effectiveness of the use of this new drug in the treatment of infections of the genito-urinary tract.

The references made to this discovery in your journal and in other medical journals have brought to us so many request for supplies of this new drug that we have deemed it desirable at once to make some hexyl resorcinol in our laboratories, and this we have now done. While we feel it premature to offer this medicament for sale without further evidence as to its clinical value, we write to say that we shall be pleased to supply it in limited quantity to any medical men who are interested in trying this new remedy.

We are, Sir, yours faithfully,

THE BRITISH DRUG HOUSES, LTD.

RED CROSS LIBRARY GIFTS.—The Library Committee of the British Red Cross Society report that during the year ending on Sept. 30th last, 1443 hospitals and kindred institutions were supplied with libraries. Sir Arthur Lawley's wireless appeal brought in over 48,000 books and magazines, and 379,000 were distributed during the year.

Obituary.

JOSEPH ARDERNE ORMEROD, M.D. OXF.,
F.R.C.P. LOND.,

CONSULTING PHYSICIAN, ST. BARTHOLOMEW'S HOSPITAL AND
NATIONAL HOSPITAL FOR PARALYSIS AND EPILEPSY;
REGISTRAR, ROYAL COLLEGE OF PHYSICIANS
OF LONDON.

DEATH has removed from our ranks a distinguished physician and scholar in the person of Dr. J. A. Ormerod, the Registrar of the Royal College of Physicians of London.

Dr. Ormerod, who was born in 1848, was the eldest surviving son of the Venerable T. J. Ormerod, Archdeacon of Suffolk, and brother of the late Miss Eleanor Ormerod, the well-known agricultural entomologist. He was educated at Rugby under Dr. Temple, and entered Oxford as a classical scholar at Corpus Christi College, where he won many classical distinctions, including the Chancellor's Prize for Latin verse. Being elected a Fellow of Jesus College, he decided to take up natural science and obtained a first class in the Natural Science Tripos in 1871. He then entered the medical school of St. Bartholomew's Hospital, where he qualified, taking also the M.B. Oxf. in 1875. He was appointed medical registrar to the hospital, took the M.R.C.P. in 1877, and was elected assistant physician in 1893, his tenure of the post of medical registrar being marked by the issue under his authorship of the medical statistics in connexion with St. Bartholomew's Hospital for the five years 1887-92. The period was one in which neurological researches in connexion with clinical medicine were proving particularly fruitful, and the famous work of Hughlings Jackson, David Ferrier, and Victor Horsley was revolutionising both accepted views and actual practice. Ormerod decided to specialise in the study of diseases of the nervous system and was elected physician to the National Hospital for Paralysis and Epilepsy. At this period the staff of the hospital comprised all those just mentioned, while Bastian and Buzzard were also among the consultants.

Both at St. Bartholomew's Hospital and at the National Hospital he displayed the same qualities of quiet acumen, correlating symptoms of all his cases with the other factors, and never fearing to give reasons for the opinions at which he arrived. His accuracy of diagnosis was very high, and those who have attended his demonstrations at the National Hospital will remember many occasions on which his methods of approaching a case, his judgment of the facts, and his prognostications of the probabilities proved a revelation to them, teaching them never forgotten lessons. An epitome of this side of Ormerod's work will be found in his *Guide to the Diseases of the Nervous System*, published now over 30 years ago. Elected a Fellow of the Royal College of Physicians in 1885, he was marked out by his learning and qualities for appointment to examinerships and official lectureships. He examined for the University of Oxford and for the Royal College of Physicians of London, delivered the Harveian Oration and Lumleian Lectures at the Royal College of Physicians of London, and was also a President of the Neurological Section of the Royal Society of Medicine. In the Harveian Oration he followed the usual custom of paying tribute to Harvey and then introducing to the notice of the audience a subject of general medical interest. He took up the vast subject of heredity in relation to disease. There has been much detailed work done along these lines during the 17 years which have elapsed since Ormerod delivered his message, but many of the questions which he then asked remain to be settled, while no better introduction to the work in this direction of Galton, Karl Pearson, Mendel, and Bateson can be found. Similarly a scholar's treatment of the great and difficult subject of hysteria marked Ormerod's Lumleian Lectures. In those

lectures he concentrated attention on the developments associated with the work of Janet and Freud, and while the researches of the former appealed more strongly to him, he did due justice to the latter's profound investigations into the problems involved. His critical spirit led him to outline, however, various objections to which Freud's theories were and are open, and beneath the polish of the essays, imposed upon him by his scholarship, it is not difficult to detect impatience with certain Freudian exuberances.

In 1909 his term of active office at St. Bartholomew's Hospital closed with his election as Registrar of the Royal College of Physicians of London, on the resignation of the late Dr. Edward Liveing. During the 15 years that have elapsed many changes and developments occurred in medical education and in every department of the work of the College, and with them came continually increasing demands on the Registrar. Ormerod never stinted himself in his devotion to his duties; his industry was unwearying and the claims of hospital and private practice were allowed to give way to the calls of his duties as Registrar, when he was appointed consulting physician to both the great hospitals where his clinical work had been done.

One of his colleagues at the College writes: "Ormerod had a full and intimate knowledge of all matters relating to the medical curriculum, and to College laws and traditions, and there was no one of the Presidents who reigned in turn during Ormerod's tenure of office, who was not glad to avail himself of his good judgment and advice. He was for many years, and up to the time of his death, a member of the Committee of Management of the Conjoint Examination Board, and at one time its chairman. And although he was of a non-assertive and retiring disposition, he never failed to form a well-thought-out and decided opinion on any College matter that came before him, and was tenacious in holding to his judgment; when he felt it his duty to do so he urged his views and opinion in the most conciliatory manner. When a decision was come to he set out at once to carry it into practice with the same ready loyalty whether or no it was in conformity with his own wishes. His amiable disposition and his kindly nature made friends of all who knew him and endeared him to those colleagues who were most closely connected with him in carrying on the business of the College. The time and labour he gave to College work is known only to them—he spared no pains and no efforts. During part of the year 1923 his health prevented him from giving his usual daily attendance at the College, but he managed to get through such part of his routine as was possible at his home and came back to regular work in November last, since which time he carried out his full duties with his usual energy and was at work till four days before his death. The influence of Dr. Ormerod's work was much more than was apparent, and his loss will be long felt and will be difficult to replace."

For so learned a man and so competent a writer Ormerod was not a profuse author, but he contributed articles on epidemic cerebro-spinal meningitis, tabes dorsalis, and hysteria to Allbutt and Rolleston's "System of Medicine," and a comparatively small number of clinical articles to THE LANCET and other medical journals. In all that he wrote he appeared as one of the leading neurologists of the country. It is significant that, when authority or support is required by writers for a statement of their own, the reference is frequently to one of Ormerod's papers.

Dr. Ormerod married, in 1878, Mary Ellen, daughter of Edward Milner, F.L.S., of Dulwich, who died at the beginning of the year. By her he had four sons and four daughters. One of his sons is Chief Constable of Sussex, and one is Professor of Greek in the University of Leeds. One of his daughters married Dr. J. B. Christopherson.

J. J. GRAHAM BROWN, M.D., F.R.C.P. EDIN.

By the death on Feb. 28th of Dr. J. J. Graham Brown, consulting physician to the Royal Infirmary, at his residence in Edinburgh, another link between the old school of medicine and the new is severed. Graham Brown was born in Edinburgh in 1853 and was a son of the Rev. Thomas Brown, D.D., who is still remembered in Scotland by his work, "The Annals of the Disruption." He was educated at the Edinburgh Academy, afterwards proceeding to Edinburgh University, where he graduated M.B., C.M. in 1875. After holding the usual hospital appointments, together with the office of Senior President of the Royal Medical Society, he went abroad and studied in the Universities of Berlin, Vienna, and Prague. On his return in 1880 he settled down in practice as a physician in Edinburgh. In 1882 he was elected a Fellow of the Royal College of Physicians of Edinburgh. During an epidemic of cholera prevailing in Spain in 1885 Dr. Graham Brown was selected as a member of the commission of investigation appointed by the Royal Society, and with Prof. Charles Sherrington and Prof. C. S. Roy carried out valuable research work on the spot. Later he collaborated with Prof. Roy in the study of the capillary blood pressure. In 1897 he was appointed assistant physician to the Royal Infirmary, Edinburgh, and in 1912 became full physician in charge of wards; this post he occupied till 1919, when he was appointed to the consultant staff. During a great part of his time at the Royal Infirmary he was medical attendant to the nursing staff of the hospital, and for the long period of 44 years he held the post as principal medical officer of the Scottish Life Assurance Company.

Dr. Graham Brown was a successful and experienced teacher of clinical medicine, and his lectures will be remembered by his students for the comprehensive detail with which they were furnished. He was also for many years University lecturer in neurology. His contributions to medical literature were considerable. Amongst them are: "A Manual of Clinical Methods," a treatise which reached its fourth edition in 1897, and "The Treatment of Nervous Diseases" (1905). In this book the author endeavoured—and his endeavour was successful—to stimulate independent thought concerning rational treatment of nervous disease. The basis of this treatment was the author's belief that the physiological function of the particular part of the nervous system which in each individual case happened to be affected determined the variety of treatment required. Contributions to journals include "The Therapeutics of Diphtheria, an Experimental Enquiry," "On Change in the Circulation Produced by Rise of Temperature," "The Perigraph, an Instrument for Delineating the Shape of the Thorax," and "Ataxia: a Symptom." In addition his non-medical writings were many and varied. He acted as President of the Royal College of Physicians of Edinburgh from the years 1912 to 1914 and in 1912 and 1918 delivered the Morison lectures to the College, and was a Fellow of the Royal Society of Edinburgh. He was at all times essentially a skilful physician of sound judgment and common sense. In manner he was modest and unassuming, and his work was at all times characterised by earnestness and accuracy.

He is survived by three sons and one daughter, the eldest son being Prof. T. Graham Brown, of the Welsh National Medical School.

THOMAS LOWE BUNTING, M.D. EDIN.,
B.H.Y., D.P.H. DURH.

Dr. Thomas Lowe Bunting, honorary physician in charge of the X ray department at the Sick Children's Hospital, Newcastle-on-Tyne, died recently from angina pectoris at the age of 57. Born at Heanor in Derbyshire, he graduated M.B., C.M. at Edinburgh University in 1889, and after a short period as asylum medical officer near Buxton he

settled down in general practice in Newcastle. In 1904 he proceeded to the M.D., gaining a gold medal for a thesis on the Histology of the Lymphatic Glands, which was the fruit of a comparative investigation over a very wide field in the animal kingdom, and his work won for him, in addition to University honours, the Fellowship of the Royal Society of Edinburgh. In 1911 he took the degree of Bachelor of Hygiene and the Diploma of Public Health, both with honours, at the University of Durham, and shortly afterwards turned from general practice to the study of radiology. Just before the outbreak of the war he had become radiologist to the Sick Children's Hospital at Newcastle. In the autumn of 1914 he was appointed radiologist to the Northumberland War Hospital, where he developed and maintained the efficient service of the department in his charge. His contributions to radiological journals on radiological methods of treatment and diagnosis of disease demonstrated both his scientific skill and his powers of deductive reasoning. Dr. Bunting was also interested in social questions, an interest which dated from his student days when he was associated with Prof. Patrick Geddes's work in founding the Town and Gown Association, for promoting students' sympathies in the welfare of the poor of Edinburgh.

In medical politics he was a leading figure in North-Eastern England, and of this branch of his activities a colleague writes: "Dr. Bunting was first interested in medico-political matters through his being on the old Northumberland Contract Committee before it was taken over by the British Medical Association. The agitation in 1912 over the National Health Insurance Act came to him as a call for work on behalf of the profession. This led to his devoting an increasing amount of thought and time to medical politics. He became secretary of the Newcastle Panel Committee and one of the elected medical representatives on the Newcastle Insurance Committee and secretary of the North-Eastern group of panel committees. In Newcastle he was the guide and adviser of the panel committee in general and of many individual doctors in particular."

ALFRED JOHN SMITH, M.B., CH.B. R.U.I.,
F.R.C.S. IREL.

THE death of Dr. Alfred Smith, professor of midwifery in University College, Dublin, occurred on Feb. 20th in Dublin after a very brief illness at the age of 59. For some years he had been much troubled with a painful and crippling form of arthritis, but his general health remained good. Two days before his death he was struck down by pneumonia, and he rapidly succumbed. A native of Co. Cavan, Alfred Smith was educated at the Cecilia-street School of Medicine in Dublin, and he also studied at Vienna, Berlin, and Leipzig. In 1884 he graduated in medicine and surgery in the Royal University of Ireland, and became M.A.O. the following year. Shortly after qualification he served for three years as assistant Master in the Rotunda Hospital under the late Sir Arthur Macan. In 1891 he was appointed professor of midwifery in the Cecilia-street School of Medicine, and since 1908 he has held the chair of midwifery in the School of University College. He was for many years gynaecologist to St. Vincent's Hospital and only retired from that post last year. He had been more than once President of the Section of Obstetrics of the Royal Academy of Medicine in Ireland, and while his health allowed he rarely missed one of its meetings. He also contributed many papers to its Proceedings, and wrote widely on his specialty in gynaecological and medical journals. A man of much vigour and originality of thought, Alfred Smith was a skilful and bold surgeon and a very successful teacher. In spite of severe physical disability in recent years he continued to perform as much of his work as was possible, and maintained a cheerful courage which commanded admiration.

CLAUDE BUCHANAN KER, M.D., F.R.C.P. EDIN.,
MEDICAL SUPERINTENDENT, CITY HOSPITAL,
EDINBURGH.

It is with deep regret that we have to announce the death of Dr. Claude B. Ker, from pneumonia, on March 4th, in his fifty-eighth year. His untimely death is a grievous loss to the City of Edinburgh and to its medical school.

Claude B. Ker was born and educated at Cheltenham and was the son of Dr. Claudius Buchanan Ker. He studied medicine at Edinburgh University, where he graduated M.B., C.M. in 1890. After holding house appointments in the Royal Infirmary and in the Simpson Memorial Hospital, he became interested in mental work and took the certificate of the Medical Psychological Association in 1891. Impressed by the possibilities presented by the study of infectious diseases his interest turned to this branch of study, and in 1896 he wrote his M.D. thesis on typhoid fever, for which he was awarded a gold medal. In that year he succeeded Dr. Wood as superintendent at the old fever hospital at High School Yards, Edinburgh, a post which was both difficult and dangerous; in fact, Dr. Wood also died of pneumonia in the prosecution of his duties. Dr. Ker saw possibilities of providing the city with a fever hospital worthy of its traditions and its medical school, and with the aid of the late Sir Henry Littlejohn, then medical officer of health, and of the late Baillie Pollard, he worked hard and unceasingly till in 1903 he saw his object achieved when the fever hospital, in its unsatisfactory position in Infirmary-street, was closed down and the splendid set of buildings to the south of Edinburgh, well removed from the city itself, were opened as the City Fever Hospital.

He became a Member of the Royal College of Physicians of Edinburgh in 1898 and was elected a Fellow of the College in 1901, and later became a member of the Council. He represented the College on the infirmary board of management and on the Scottish Board of the College of Nursing. He was University lecturer in infectious diseases. As a research worker he showed the most thorough care in details, and he was a pioneer in introducing in this country the Schick test. He was the author of "A Manual of Fevers" and "Infectious Diseases, a Practical Textbook," and by these two books he will be long remembered. "A Manual of Fevers" was first published in 1911 and the second edition appeared in 1922. Although primarily intended for the use of students, the manual has more than justified the hope expressed by the author in his first preface, "that it might not cease to be useful when its owner had entered upon general practice." The first edition of "Infectious Diseases" appeared in 1909. It is an authoritative and valuable book dealing with the diseases commonly met with in the British Isles, and is clearly the work of a skilful, observant, and experienced physician. The second edition, adequately supplemented by a study of recent contemporary literature, was published in 1920. His contributions to medical journals were numerous, and include "Naphthols in Enteric Fever," "An Outbreak of Typhus Fevers," "Isolation and Quarantine Periods." To our own columns he made editorial contributions whenever requested, and it happens pathetically that one such article appears this week. His medical reputation in the specialty of infectious diseases is not confined to Britain, for his works are well known abroad, especially in America, as University lecturer on infectious diseases.

We are indebted to Dr. Andrew Balfour for the following appreciation. He writes: "I would like to tell, albeit briefly and imperfectly, what manner of man was 'Claude B' and how he came to gain the affection and esteem of all who came closely into touch with him. Ker was intensely alive, intensely human, full of humour and sympathy, and utterly devoid of anything savouring of advertisement or self-seeking. Withal he was a man of great force of

character with strong likes and dislikes and capable—very capable, of standing up for what he conceived to be the right. Yet he very rarely found himself in conflict, for he possessed much tact and discretion and a store of patience which time and again stood him in good stead. I first met him in 1896 when, having been appointed assistant physician at the Edinburgh City Hospital, I called at the Old Pest House, as we called it, at the foot of Infirmary-street to be interviewed by the medical superintendent. I was shown into a small room and presently there entered with a brisk step and a curious swing of the body a man of medium height who wore a monocle through which an eye afflicted, though not unpleasantly, by an internal strabismus surveyed me searchingly. He wore a blue velvet tasselled skull cap, was clad in a long white overall, and carried a wooden stethoscope of prodigious length. He spoke like an Englishman, kept flicking cigarette ash on the floor, and his manner was decisive, even a little brusque. He seemed to me rather nervous, and I gathered he did not quite approve of my appointment, which had been made at the instance of Sir Henry Littlejohn. Certainly he made it quite plain that I was there to carry out his instructions, though he indicated, also quite clearly, that he realised I might have views of my own and that he was prepared to accord them every consideration. As I told him long afterwards, my first thought was, 'How can I work under this man?' Yet very soon I had fallen, as did all his assistants and all his residents, under the spell of his personality. I realised that his was a choice spirit, that he was possessed of much originality of mind, that he was well-read and erudite, that he had wide interests, and that he was gifted with vision, though in no sense of the word a visionary. I had some slight acquaintance with French history and I found that Ker was a great student of the Napoleonic era and I never tired of hearing him descant on Buonaparte's strategy and recounting how he had secured the prints, statuettes, and relics with which his room was filled. Beyond doubt he might have been an admirable professor of military history, for he had a flair for tactics, and it was probably his military bent which led him to take a Commission, first in the Volunteers and then in the Territorials. He was interested in sport and athletics, especially in Rugby football, had a keen sense of humour, and wrote most amusing and delightful letters in verse and prose.

"We soon formed a friendship which stood the test of time and distance, and the memory of which will ever remain precious and fragrant. But Ker had a host of friends. It was the custom then, and I understand it remained a custom, for his old residents to gather in his room on Sunday nights. No more profitable evenings can be imagined than these informal gatherings in the venerable building full of memories of Sir Walter Scott, of the anatomist Knox, and of Burke and Hare, the West Port murderers; Ker delighted in the history of the dingy pile, as he delighted in everything pertaining to Edinburgh, for, though not a son of the city, though not a pure-blooded Scot, and though educated at an English public school, the fascination of Auld Reekie held him in its grip.

"It was largely Ker's efforts that made the present City Hospital a credit to Edinburgh, while it is undoubtedly due in the main to him that it attained such a high degree of efficiency. No man was ever more popular with his staff. He had a way of getting the best out of them and set an example of devotion to duty and of tireless yet painstaking energy which acted as a stimulus to all. He found relaxation chiefly in his family life, in travel, and in the society of his friends. At home he was a member of a small literary club which, beginning as the Heptagon, became an Octagon. Its membership was confined to a few medical men who met at each other's houses. He never missed a meeting throughout the 25 years of the club's existence."

Stricken with influenza Ker would not give in, for he had under his charge a desperate and septic case of scarlet fever in which he was deeply interested. Despite vile and inclement weather he was up and about until literally driven to the bed where he died. His memory will remain ever green in the hearts of those who knew his worth and valued his company and his friendship.

The fine City Hospital stands as a fitting memorial to his memory. He is survived by his widow, two sons and three daughters, to whom we extend our sympathy.

Medical News.

UNIVERSITY OF CAMBRIDGE: Pinsent - Darwin Studentship in Mental Pathology.—This studentship was founded in 1924 by the benefaction of Mrs. Pinsent and Sir Horace and Lady Darwin for the purpose of promoting research into any problem which may have a bearing on mental defects, diseases, or disorders. The studentship is of the annual value of about £200 and is tenable for three years in the first instance. The student may be of either sex and need not be a member of the University of Cambridge. He shall engage in original research in Cambridge or elsewhere, but may, subject to the consent of the managers, carry on educational or other work concurrently. Further particulars of the studentship may be obtained from the Registry of the University of Cambridge, and applications for appointment to the studentship should be sent before May 1st, 1925, to the Secretary, Pinsent-Darwin Studentship, Psychological Laboratory, Cambridge.

UNIVERSITY OF LONDON: London Hospital Dental School.—A special lecture Concerning Misplaced Teeth will be given by Mr. W. H. Dolamore, L.D.S., on Tuesday, March 24th, at 5 P.M., in the anatomical theatre of the hospital. Members of the dental profession and students are invited to attend.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following demonstrations of specimens in the Museum will be given by Sir Arthur Keith in the theatre of the College in Lincoln's Inn-fields on Fridays at 5 P.M.: March 20th, Specimens illustrating the Surgical Anatomy of the Middle Ear; March 27th, Specimen illustrating the Commoner Congenital Malformations of the Lower Limb; April 3rd, Acromegaly and Allied Disorders of Growth. The demonstrations are open to advanced students and medical practitioners.

DISEASES OF CHILDREN.—A post-graduate holiday course of clinical lectures, arranged by the Faculté de Médecine de Paris, on diseases of children will be held at the Hôpital des Enfants Malades, from April 6th to 18th. Further information may be obtained from the hospital, 149, Rue de Sèvres, Paris.

GUY'S HOSPITAL DENTAL SCHOOL.—A dental travelling scholarship, enabling the holder to take out a course of at least six months' practical work in dental surgery at one or more colonial or foreign dental schools, will be awarded by the treasurer, upon the recommendation of the Dental Council, in July, 1925. Candidates must be registered Licentiates in Dental Surgery of the Royal College of Surgeons of England or holders of a dental degree of a British university who have been educated at Guy's Hospital Dental School. The total value of the scholarship will be £250. Further information may be obtained from the Treasurer, Guy's Hospital, London, S.E. 1.

ROYAL DEVON AND EXETER HOSPITAL.—It is hoped that during the present year a department for the treatment of cancer will be opened at this hospital. A deep therapy apparatus has been fitted up, and arrangements are being made for a supply of radium. Some of the beds have had to be closed for lack of money.

BRIGHTON: ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN.—Erected in 1881, this fine building in the Dyke-road, Brighton, required important replacements during the past year, so that the year ended with a bank overdraft of £1094. At the annual meeting of the governors on Feb. 27th Mr. Harry Preston, who presided, promised to undertake the liquidation of the debt. The governors accorded cordial recognition for the help rendered by the Sussex Provident Scheme to the finances, and agreed to make a contribution towards the salary of an appeal secretary for the fund, as it was realised that the membership of the scheme might be greatly extended to the advantage of all the co-operating hospitals.

CHELSEA CLINICAL SOCIETY.—A meeting of this society will take place at the Club Room, St. George's Hospital (entrance in Knightsbridge), on Tuesday, March 17th, at 8.30 P.M. precisely, when a discussion on Some Diseases Common to Old Age will be opened by Dr. Leonard Williams and Mr. Kenneth Walker.

Mr. Percy Dunn, on resigning the editorship of the *Bulletin of the Fellowship of Medicine*, has been unanimously elected by the Executive Committee an honorary member of the Fellowship, in recognition of his services during the past five years.

ITALIAN CONGRESS OF MEDICAL RADIOLOGY.—The Sixth Italian Congress of Medical Radiology will be held in Trieste from May 7th to 10th. Communications will be read on the Radiology of the Biliary Passages, by Prof. Pasquale Tandoia, of Naples; on the Radiology of Lung Affections, by Prof. G. Pesci, of Genoa; and on the Radiotherapy of the Endocrine Glands, by Prof. E. Milani, of Rome. Full particulars may be obtained from the President of the Congress, Dr. Maximilian Gortan, at the Ospedale Civico Regina Elena, Trieste, Italy.

ROYAL SOCIETY OF MEDICINE.—The adjourned discussion on the opening papers of the general debate on Non-Specific Disturbances of Health due to Vitamin Deficiency, which was held by the Society on Feb. 16th, will be resumed on Monday, March 23rd, at 5.30 P.M., at 1, Wimpole-street, W. The papers read on Feb. 16th by Dr. Leonard Williams, Colonel Robert McCarrison, Dr. W. Cramer, and Dr. G. M. Findlay were reported in THE LANCET of Feb. 21st, p. 385. The original speeches can be read in full in the March number of the Society's Proceedings, and those who wish an epitome can obtain galley slips on application at the Society's office. The subject will again be opened by Dr. Williams, and the first speakers in a general discussion of these papers will be Dr. William Hunter and Dr. Robert Hutchison.

Nichols Prize.—In accordance with the will of the late Dr. Robert Thomas Nichols, the Royal Society of Medicine will offer, every three years, a prize of £250, open to any British subject, for the most valuable contribution towards the Discovery of the Causes and the Prevention of Death in Childhood from Septicæmia. The first award of the prize has been made to Dr. George Geddes, of Heywood, Lancs, for his essay entitled the Causation, Prevention, and Treatment of Puerperal Septicæmia. Work submitted for the next award should reach the secretary of the society not later than Oct. 1st, 1927, and must be marked "Nichols Prize." It must be typewritten or printed, in English, and accompanied by the name and address of the author. Work already published may be submitted, provided that publication was not earlier than Oct. 1st, 1924. If no work of sufficient merit be submitted, the prize will not be awarded.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A discussion on Post-graduate Study in London will be held at the house of the Royal Society of Medicine, 1, Wimpole-street, W., on March 18th, at 6 P.M. Sir Arbuthnot Lane will preside, and the freest criticism will be welcomed of the present facilities offered through the Fellowship with suggestions for their improvement. It is hoped that a large attendance of the medical profession, whether resident at home or overseas, will take part in the discussion.—Syllabuses of the following courses during March are now available: A course at the Brompton Hospital for Consumption and other Diseases of the Chest from March 16th to 28th; special reference to treatment by artificial pneumothorax will be made, but other diseases of the lungs besides phthisis as well as diseases of the heart will be dealt with and illustrated by frequent demonstrations of cases.—A course in Gynaecology will be held at the Chelsea Hospital for Women from March 16th to 28th, which will include clinical lectures and demonstrations and the opportunity of witnessing typical operations.—An intensive post-graduate course, including all departments of the practice of an active general hospital, will be held at the Royal Northern Hospital from March 23rd to April 4th. It will comprise demonstrations, clinics, operations, exhibitions of selected cases as well as formal lectures. Application for admission to the course should be made by March 16th.—During April there will be courses held at the Queen's Hospital for Children, St. Mark's Hospital for Diseases of the Rectum, and at the Hampstead General Hospital.—A practical course in Anæsthetics is being arranged and will begin approximately on March 23rd. The course will continue for a week, and opportunity will be afforded for post-graduates to obtain instruction in throat, nose, dental, abdominal, and nerve anæsthesia. Early application is desirable. Further information as to courses may be obtained from the Secretary to the Fellowship, 1, Wimpole-street, London, W.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this Society will be held to-day, Friday, at the Miller General Hospital, Greenwich, S.E., at 8.45 P.M., when a paper on Some Interesting Abdominal Cases will be read by Mr. Hugh Davies. Dr. H. S. Knight, the President, will occupy the chair.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—The area of operations of the King's Fund has been extended from a radius of nine miles of Charing Cross to a radius of 11 miles of St. Paul's Cathedral. Hospitals within this area, desiring to participate in the grants made by the Fund for the year 1925, must make application before March 31st to the Hon. Secretaries of the Fund, at 7, Walbrook, E.C. 4. Applications will also be considered from convalescent homes which are situated within the above boundaries or which, being situated outside, take a large proportion of patients from London.

ENTRY OF TUBERCULOUS IMMIGRANTS INTO SOUTH AFRICA.—A resolution has been adopted at a recent meeting of the Council of Public Health of Pretoria to the effect that more drastic steps should be taken to prevent tuberculous immigrants from entering the Union of South Africa, and that the plan adopted by Canada should be followed by the Union. Under this scheme all immigrants are examined by the ship's surgeon during the voyage, and a report on each is furnished to the immigration officer and port health officer at the port of arrival.

ROYAL SANITARY INSTITUTE.—A sessional meeting will be held on Friday, March 27th, in the Town Hall, Leicester, when discussions will take place on Maternity and Child Welfare Work, to be opened by Dr. Helen Dent, maternity and child welfare medical officer, and Mrs. C. J. Bond, J.P., and on Smoke Abatement, to be opened by F. G. McHugh, chief sanitary inspector. The chair will be taken at 3.30 P.M. by Prof. H. R. Kenwood. On Saturday, March 28th, visits will be paid to local health centres and various public institutions. Those proposing to attend the meetings and the visits should notify the hon. local secretary, Dr. C. Killick Millard, medical officer of health, Health Department, Grey Friars, Leicester, not later than March 20th.

ARTIFICIAL SUNLIGHT FOR LEEDS.—In THE LANCET of Jan. 3rd attention was called to the need of "artificial sunlight" treatment at Leeds General Infirmary. The lack is now about to be supplied by two donors, one of whom has undertaken to provide all the necessary apparatus, while the other has contributed a sum sufficient to erect a new building which will house the deep X ray therapy department already in existence and the new appliances for the adoption of the ultra-violet ray treatment. The new building will contain five large rooms equipped for the sunlight treatment, together with dressing and waiting rooms and offices, and five cubicles for X ray treatment of malignant disease. It is expected that the extension will be completed in about three months.

A GROUP of medical officers of health for the London boroughs have visited the Oxo factory, where the processes of manufacture of the products were explained and a demonstration was given of the way in which the "oxoid" gland preparations are physiologically standardised. A cinema film of life on the Oxo cattle farms was also shown. Dr. D. L. Thomas, M.O. for Stepney, in returning the thanks of the visitors for an interesting afternoon, stated that they were all impressed with the high standard of hygienic conditions existing in the factory, the quality of the preparations, and the trouble taken in looking after the comfort and happiness of the workers. We understand that further visits are being arranged, and any of our readers desirous of availing themselves of these opportunities should communicate with Oxo Limited, Southwark Bridge, S.E.

THE LATE DR. J. W. SMITH.—John Williamson Smith, M.D. Glasg., of Radcliffe, Lancs, honorary ophthalmic surgeon to the Bury Infirmary, died in distressing circumstances on Feb. 28th as the result of accidental poisoning by the exhaust gases of his motor-car. On the previous afternoon he was found unconscious in his garage, and medical aid did not avail to save his life. It was stated at the inquest that while making some adjustment to his car, as the engine was running, he had inhaled the carbon monoxide of the exhaust fumes. Dr. Smith was a native of Glasgow, and was 45 years of age. He graduated M.B., Ch.B. at Glasgow University in 1902, and obtained the M.D. with commendation in 1908. He practised for 22 years in Radcliffe, and in addition to the work of general practitioner he specialised in diseases of the eye. His sad and untimely death is deeply regretted by his colleagues and friends.

METROPOLITAN ASYLUMS BOARD.—A three-months course of lectures and demonstrations dealing with hospital administration for the Diploma in Public Health will be given at the North-Western Hospital, Lawn-road, Hampstead, N.W., by Dr. E. W. Goodall, medical superintendent, on Mondays and Thursdays at 4.45 P.M., and alternate Saturdays at 10.30 A.M., beginning Monday, April 6th. This course complies with the requirements of the revised regulations of the General Medical Council.

PROBLEMS OF HOSPITAL FINANCE AT PLYMOUTH.—At a recent conference of members of the boards of management of the local hospitals, the Plymouth Voluntary Hospitals Committee, and others, Lord Onslow, the chairman of the Voluntary Hospitals Committee, expressed his belief that mass collections were the only means by which a really considerable increase of income could be obtained. It was essential to broaden the basis of subscription and to reduce expenditure by organisation and co-operation. He promised to discuss with his colleagues the possibilities of recommending a Government grant for the training of nurses. Mr. S. R. Lamb, explaining the working of the penny-in-the-pound system in that city, said it was neither an insurance society nor a slate club, and it was not pretended that it was actuarially sound.—The annual report of the Plymouth Voluntary Hospitals Committee records that the two closed wards at the South Devon and East Cornwall Hospital have been reopened, and that a ward in the Homoeopathic Hospital has been brought into use. The penny-in-the-pound scheme, launched in 1923, has progressed beyond expectation and now has well over 20,000 members and promises to be much larger, since the scheme is now establishing itself in the country districts. During the past financial year the contributory scheme patients cost the hospitals £8697, towards which it provided £7632.

DONATIONS AND BEQUESTS.—Mr. William Morgan Lewis, J.P., colliery proprietor, Cardiff, left £1250 to King Edward VII. Hospital, Cardiff, for the endowment of a Dorothy Lewis bed, in memory of his late daughter.—Mr. Charles Arthur Head, Stockton-on-Tees, left £500 to the Stockton and Thornaby Hospital, and £100 each to the Ropner Convalescent Home and the National Society for the Prevention of Cruelty to Children.—The Right Hon. William Drennan Andrews, a judge of the Irish High Court, besides other bequests, left £500 to the Royal Victoria Eye and Ear Hospital, Dublin, £300 each to Sir Patrick Dun's Hospital, the Rotunda Hospital, the Royal Hospital for Incurables, the National Children's Hospital, the Stewart Institution for Idiot and Imbecile Children, and the Cumber District Nursing Society, Dublin, and £200 each to the Charitable Infirmary, Dublin, and the Royal National Hospital for Consumption for Ireland.—Dr. John B. Stelfox, of Birkdale, has made a gift of £2000 to the North of England Children's Sanatorium at Southport for the endowment of two beds for the benefit of children of Middleton and Lees.—The students of the University of Liverpool on Panto Day raised £3800—a record figure—for the hospitals.—Sir William Earnshaw Cooper, C.I.E., Guernsey, who left estate of the gross value of £55,085, gave 30,000 rupees to the Ramsay Hospital, Naini Tal, India, for the maintenance of the Cooper Ward for poor and non-paying patients; 10,000 rupees each to the Summer Home for Soldiers' Children, Mussori, and Allahabad Free School and Orphanage. After the fulfilment of a number of personal bequests, the residue of the property to his wife for life, and then as to one-half to Dr. Barnardo's Homes.—An anonymous donor has given £3500 in trust securities to the Manchester Royal Infirmary, the income to be used for the purchase of apparatus for the X ray department.—The Manchester University students' "rag" on Shrove Tuesday produced some £5808 for the medical charities of the city, or more than double the collection last year.—By the will of the late Mrs. Margaret Alice Dalton-Burgess, of Bristol, the testator left £2000 to the Zenana Bible and Medical Mission, and after certain bequests and private legacies the residue of the estate to, amongst other charities, the Cosham Memorial Hospital, Bristol, the Bristol Eye Infirmary, the Children's Hospital at Bristol, the Bristol Royal Infirmary, the Bristol General Hospital, the Clifton Zoological Gardens, and a further £2000 to the Zenana Bible and Medical Mission.—Mrs. Sarah Scholes Wrigley, of The Wood, Windermere, Westmorland, left £1000 each to the Royal Asylum, Lancaster, and the Royal National Lifeboat Institution, £500 each to the Westmorland County Hospital, Kendal, the Dispensary Hospital, Bury, the Manchester Royal Eye Hospital, the Manchester Domestic Mission, Manchester College, Oxford, the United Kingdom Beneficent Association, Railway Servants' Benevolent Institution, the Brompton Cancer Hospital, London, the Queen's Hospital for Sick Children, Hackney, London. Half of the residue of her property, after private bequests, she left equally between the above-named charities. The total sum available for charities will amount to about £40,000.

MENTAL AFTER-CARE ASSOCIATION.—The annual meeting of this Association will be held on Wednesday, March 18th, at 3 P.M., at the Clothworkers' Hall, Mincing-lane, London, E.C. The chair will be taken by Sir Charles C. Wakefield, President of the Association.

MEMORIAL TO DR. F. W. A. GODFREY.—An appeal for a fund for establishing a memorial to the late Dr. F. W. A. Godfrey has been issued by the Mayor of Scarborough and other influential local signatories, the object being to associate with Dr. Godfrey's name an endowment of new beds in the Scarborough Hospital, or to make any other permanent provision for an institution to whose interests Dr. Godfrey was for 30 years devoted. Contributions amounting to nearly £500 have already been received, and cheques payable to the Godfrey Memorial Fund should be sent to Mr. William Boyes, the Mayor of Scarborough, at the town hall of the city.

SPIRITUAL HEALING.—In July, 1924, a group of medical men was formed to make an investigation into this subject in order to prepare and issue a statement on the question. Conferences with representatives selected by the churches are being held, and other avenues of research are being explored. The members of the group are: Sir Robert Armstrong-Jones, Dr. Helen Boyle, Dr. H. C. Bristowe, Dr. William Brown, Dr. Charles Buttar, Mr. W. McAdam Eccles, Dr. Letitia Fairfield, Dr. E. R. Fothergill (chairman), Dr. J. G. Porter-Phillips, Dr. Mary Scharlieb, Sir J. Purves-Stewart, Mr. E. B. Turner, Dr. Jane Walker, and Dr. Stanley Bousfield, hon. secretary, to whom communications may be addressed at 10, Albion-street, London, W. 2.

The Services.

ROYAL ARMY MEDICAL CORPS.

MILITIA.

Capt. J. A. Pridham to be Maj.

TERRITORIAL ARMY.

Capt. R. W. Smith resigns his commn. and retains his rank.

Capt. J. H. Iles (late R.A.M.C.) to be Lt.

L. C. F. Chevens to be Lt.

Lt.-Col. H. J. Walker resigns his commn. and retains his rank.

Lt. F. R. Daniel (late R.F.A.T.F.) to be Lt.

Supernumery for Service with O.T.C.—Capt. A. Fowler (late R.A.M.C., S.R.) to be Capt., for service with the Medical Unit, Aberdeen University, O.T.C.

Sanitary Companies.—Capt. (Prov.) A. Massey resigns his commn.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt. M. D. Mackenzie, from the Active List, to be Capt.

ROYAL AIR FORCE.

L. C. Palmer-Jones and T. W. Wilson are granted short service commissions as Flying Officers, for three years on the Active List.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED FEB. 28TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 141; scarlet fever, 1729; diphtheria, 969; enteric fever, 33; pneumonia, 1306; puerperal fever, 54; cerebro-spinal fever, 7; acute poliomyelitis, 7; acute polio-encephalitis, 1; encephalitis lethargica, 61; relapsing fever, 1; dysentery, 3; ophthalmia neonatorum, 106. There were no cases of cholera, plague, or typhus fever notified during the week. The number of small-pox cases showed a decrease of 8 from the number for the preceding week. Twenty cases were notified from Derbyshire, 7 from Northumberland, 30 from Notts, 36 from Yorks, North Riding (Middlesbrough, C.B., 34), and 13 from Yorks, West Riding.

Deaths.—In the aggregate of great towns, including London, there were 4 deaths from enteric fever, 98 from measles, 18 from scarlet fever, 120 from whooping-cough, 39 from diphtheria, and 346 from influenza, as compared with 352, 354, 291, and 202 in the four preceding weeks. In London itself the deaths from influenza numbered 64, from whooping-cough 37, and from diphtheria 13.

Parliamentary Intelligence.

HOUSE OF LORDS.

TUESDAY, MARCH 10TH.

THERAPEUTIC SUBSTANCES BILL.

The Marquess of SALISBURY (Lord Privy Seal), in moving the second reading of the Therapeutic Substances Bill, said that it had passed through their lordships House last session very much in its present form, but unfortunately it did not pass through the House of Commons. The principle of the measure was to prevent users of certain therapeutic substances from being misled as to their character. If it was necessary to ensure a proper standard in regard to ordinary substances it was specially necessary in the case of therapeutic substances on which the health of the users depended. The medical profession could not be rightly advised as to what they were prescribing unless there was some standard in regard to these substances on which reliance could be placed. Some of these substances were highly poisonous unless they were prepared in properly graded quantities. These substances included sera, vaccines, and special preparations such as salvarsan. In many other countries, including Norway, Sweden, France, Germany, Italy, Spain, and the United States, the manufacture of these substances was subjected to most rigid inspection. Denmark had gone still further and there such substances were only allowed to be prepared in State institutions. The procedure proposed in the Bill was that these substances should be subject to licences both in respect of the persons who prepared them and the place in which they were prepared. The conditions under which they could be prepared were to be laid down in regulations which would be laid before Parliament. The regulations would be made by a joint committee consisting of the Minister of Health, the Secretary for Scotland, and the Minister for Home Affairs in Northern Ireland. An advisory committee was also to be appointed consisting of representatives of the three departments named and, in addition, one representative each of the Medical Research Council, the General Medical Council, and the Pharmaceutical Society. Certain substances used for research purposes would be obtainable for that purpose under licence at strengths other than the standard strength used for medical purposes. This subject had been before the appropriate authority of the League of Nations and they had decided to move the various Governments to protect the standard of purity of these therapeutic substances.

Viscount HALDANE called attention to Subsection 2 of Clause 3 which he said compelled a man of science who needed these substances for research to obtain a special licence in order to use them. In many cases scientists would want them at short notice, and from what he knew of these men they would not apply for licences. Thus, this subsection might interfere with very valuable research work, and he suggested that a special instruction should be given to the Government department concerned that where a scientist required a small quantity of a particular substance for the purpose of research, he should be allowed to obtain it without the necessity for a licence.

The Marquess of SALISBURY said the point raised by the noble Viscount would be most carefully considered by the Government, and he would see whether it was possible to deal with the matter in committee.

The Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 4TH.

Medical Certificates for Motor Drivers.

Mr. STEPHEN MITCHELL asked the Minister of Transport if he would introduce legislation to compel all applicants for a licence to drive motor vehicles to produce a medical certificate as to their mental and physical fitness.—Colonel W. ASHLEY replied: I am disposed to agree with the conclusion reached by the Departmental Committee on the Taxation and Regulation of Road Vehicles, as set out in their second interim report, that the difficulties in giving effect to the suggestion contained in my hon. friend's question render its adoption impracticable.

Royal (Dick) Veterinary College, Edinburgh.

Mr. J. B. COUPER asked the Secretary for Scotland the amount of grant paid annually by the Scottish Board of Agriculture to the Royal (Dick) Veterinary College, Edinburgh; and whether it will be affected by the decision to withdraw the annual grant from the Glasgow Veterinary College.—Sir J. GILMOUR replied: The annual grant paid to the Royal (Dick) Veterinary College by the Board is £4000,

orsuchsmallersum as will meet the deficit on the maintenance of the College. The grant sanctioned for the current year is £3722. The reply to the second part of the question is in the negative.

THURSDAY, MARCH 5TH.

Permanent Medical Appointments.

Major-General Sir RICHARD LUCE asked the Minister of Pensions what steps were being taken to make permanent medical appointments under the Ministry; and if English nationality and active service in the late war would be taken into special consideration in making selections for permanent appointments.—Lieut.-Colonel G. F. STANLEY (Parliamentary Secretary to the Ministry of Pensions) replied: It has been decided to create 48 permanent established appointments on the medical staff of the Ministry and to fill those appointments from the existing full-time temporary medical staff. All members of the full-time temporary staff who are within the prescribed age-limit, of eligibility have been notified of the conditions of the appointments, and a Selection Committee presided over by the First Civil Service Commissioner is at present engaged in interviewing a selected number of the candidates. All candidates must satisfy the general rule of the Civil Service as regards British nationality and must have served in His Majesty's forces in the late war.

Ex-Service Men in West Ham Mental Hospital.

Mr. GROVES asked the Minister of Pensions whether the 52 ex-Service men, at present inmates of the West Ham mental hospital at Goodmayes, Essex, were chargeable to the local Poor-law union or whether they were maintained from national funds; and if so, to what amount weekly was the local authority reimbursed.—Lieut.-Colonel G. F. STANLEY replied: I understand that there are 50 Service patients, that is, men whose disability is due to war service, in the hospital referred to for whom the Ministry are paying the cost of maintenance and treatment at the rate of 33s. a week for each patient, in addition to allowances for wives or dependents.

Pension Assessment Appeals.

Mr. PIELOU asked the Minister of Pensions the number of appeals made to the assessment appeals tribunals from Jan. 1st to Dec. 31st, 1924, showing the number allowed by the tribunals and the number disallowed.—Lieut.-Colonel G. F. STANLEY replied: During the period referred to 35,390 appeals were decided by the assessment appeal tribunals, thus giving a proportion (excluding statutory final awards) of approximately one appeal out of every seven cases of final award notified. In 13,560 cases either the appeal was disallowed or the Ministry's assessment was reduced, or the appeal was not proceeded with by the appellant. In 11,360 cases the finality of the award was confirmed, though the assessment was raised, and in 10,470 cases the appellant succeeded to the extent that the tribunal decided that the cases were not yet suitable for final award.

Double Inquiries in Coroners' Courts.

Mr. DIXEY asked the Home Secretary whether he was aware that the present system of double inquiries of the coroner's court and the police court in murder trials, which often were held simultaneously, was very unsatisfactory to all concerned; and what steps he proposed to take with regard to the same.—Sir W. JOYNSON-HICKS replied: I hope to introduce a Bill very shortly to amend the law relating to coroners' inquests which will deal with this matter.

The General Medical Council and Unregistered Practitioners.

Mr. ARTHUR GREENWOOD asked the Prime Minister whether his attention had been called to the warning notice issued to registered medical practitioners by the General Medical Council purporting to give a summary of the resolutions and decisions of the Council upon forms of professional misconduct; whether he was aware that in consequence of the issue and circulation of that notice registered medical practitioners were deterred from assisting, by administration of anaesthetics or otherwise, qualified but not registered practitioners of osteopathy, bone-setting, and other new forms of treatment of human ailments; whether he was aware of the feeling of dissatisfaction amongst the general public and also amongst many medical practitioners with the exercise by the General Medical Council of its functions and powers conferred by Statute of 1858; and whether he was prepared to set up a commission or departmental committee of inquiry into the operation and administration of the various medical Acts, and the exercise by the General Medical Council of its functions and powers under such Acts, with a view to the introduction of such legislation as might be necessary to ensure the recognition and legal regulation in this country of osteopathy, bone-setting, and other new methods of treatment, and to safeguard both qualified practitioners and the general public.—Mr. CHAMBERLAIN replied: I understand that the warning

notice to which the hon. Member refers was adopted virtually in its present form by the General Medical Council in 1897 and subsequent alterations have been merely verbal. The answer to the second part of the question is in the affirmative. As regards the third and fourth parts, while the application of the principles laid down in the notice to particular cases may have given rise to criticisms, there is no evidence of any general dissatisfaction among the public or the medical profession, and I see no necessity for the appointment of any commission or committee such as the hon. Member suggests.

Mr. GREENWOOD: Would the right hon. gentleman be good enough to ask the Prime Minister whether he would receive a deputation of some Members of this House?

Mr. CHAMBERLAIN: I suggest that the most convenient and practical course would be for him to make representations to the Minister of Health.

Delay in Payment of Sickness Benefit.

Colonel DAY asked the Minister of Health whether he was aware of the complaints arising from delay in payment of sickness benefit under the National Health Insurance Act to sick insured persons; and, if so, whether he would appoint a departmental committee to inquire into this matter.—Sir KINGSLEY WOOD replied: My right hon. friend is aware that some complaints have been made of delay in payment of benefit to insured persons who fall sick, and on receipt of any such complaints action is taken departmentally with the approved society concerned. My right hon. friend does not think it necessary to set up a departmental committee on the subject, which has already been brought to the notice of the Royal Commission on National Health Insurance.

Milk and Dairies Acts.

Mr. BARNES asked the Minister of Health whether he has decided to ask Parliament to continue the Milk and Dairies (Amendment) Act, 1922, or whether he was now prepared to recommend Parliament to put the Milk and Dairies Act of 1915 into operation.—Sir KINGSLEY WOOD replied: It is not proposed to ask Parliament to postpone further the operation of the Milk and Dairies (Consolidation) Act, 1915, which, under the provisions of the Act of 1922, will come into operation on Sept. 1st next. The other Act named in the question is not a temporary measure and will continue in force.

The Earl of DALKEITH asked the Secretary for Scotland whether it was proposed to postpone the bringing into operation of the Milk and Dairies (Scotland) Act, 1914; and, if not, whether any decision had yet been arrived at as to the appointed day on which it was to be brought into operation.—Sir J. GILMOUR replied: The reply to the first part of the question is in the negative. It is proposed to bring the Act into operation on Sept. 1st, 1925.

Treatment of Diabetes in Scotland.

The debate was resumed on the motion for the second reading of the Public Health (Scotland) Amendment Bill.

Mr. WILLIAM ADAMSON and Dr. DRUMMOND SHIELDS again urged that the Bill should be made applicable to other diseases besides diabetes and that it should be possible to extend its operation without the necessity for a fresh Act of Parliament.

Captain ELLIOT (Parliamentary Under Secretary of Health for Scotland) said that it was the express desire of the local authorities that the general power which the hon. Members desired should be included in the Bill should be left out of it. Their reason was that while they were willing to bear the small expense involved under the present measure they thought that if the power was to be extended it ought to be discussed in Parliament and form the basis of new legislation instead of being brought about in the somewhat surreptitious manner involved in the procedure by Order in Council laid on the Table of both Houses. The analogy of England and Scotland was not really justified because the English Act only made a temporary provision, whereas this Bill was a permanent one to deal with diabetes. He thought that they were all anxious to see this Bill passed to see the position regularised, and to see this wonderful new remedy made freely and legally available to all sections of the community.

After further debate the second reading of the Bill was agreed to by 272 votes to 115.

MONDAY, MARCH 9TH.

Opium Production in India.

Mr. BUCHANAN asked the Under Secretary of State for India whether the Government of India was aware that the use in India of opium was supported by British officials as a well-established and, on the whole, not an injurious habit; and what steps he proposed to take to ensure that the use of this drug should be discontinued.—Earl WINTERTON replied: The view of the Government of India, based upon the findings of the Royal Commission which investigated the consumption of opium in India in 1895, is that centuries

of inherited experience have taught the people of India discretion in its use, which for the most part is without injurious consequences. The distribution of opium is strictly controlled in accordance with the provisions of The Hague Convention, 1912. My noble friend does not propose to interfere with the discretion of the Government of India and Provincial Governments in the exercise of this control.

Effect of Preservatives in Food.

Mr. HARDIE asked the Minister of Health whether he was aware that on p. 19, para. 59, of the Final Report on Preservatives and Colouring Matters in Food it was stated that it was evident that individuals might consume quite considerable quantities of preservatives in the course of an ordinary day's diet and that it was easy to imagine a reasonable meal which might contain 20 or even more grains of boric acid besides other preservatives; and whether, in the opinion of his official adviser, the effects of 20 gr. of boric acid were good or bad for the average individual consumer.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: My right hon. friend is aware of the statement referred to by the hon. Member. He is advised that the continued consumption of such quantities of boric acid as those mentioned would be likely to have a deleterious effect.

The Danger of Toy Pistols.

Colonel DAY asked the Home Secretary if his attention had been drawn to the danger that the public were exposed to by the use of toy pistols, sold at a cost of a few shillings, which had proved the subject of a recent inquest; and, in view of these disclosures, would he consider introducing legislation to regulate the sale and use of these dangerous toys.—Sir W. JOYNSON-HICKS replied: I have no reason to think that the danger to the community arising from toy pistols is sufficiently great to justify the extension to them of the provisions of the Firearms Act, and I do not think I could initiate legislation for this purpose.

Accidents to Tramway Traffic Controllers.

Colonel DAY asked the Minister of Transport the number of traffic controllers employed by the London County Council on their tramway services who had met with accidents while engaged in their employment during the last 12 months; and whether the accidents had been caused by motor or other vehicles.—Colonel W. ASHLEY replied: I am informed by the London County Council that during the 12 months ended Feb. 21st last two tramway traffic regulators and two ticket inspectors in the employment of the Council were injured, in one case fatally. All these accidents were, I understand, caused by motor vehicles.

Defective Children.

Mr. STAMFORD asked the President of the Board of Education the number of defective children of school age under the heads of blind, deaf and dumb, feeble-minded, tuberculosis (pulmonary), cripples (tubercular), cripples (other than tubercular), and other physical defectives, together with the special school accommodation available for each class of case.—Lord E. PERCY replied: I can only give the figures based upon the classification adopted for the purpose of the returns made to the Board. On this basis the figures are:—

	Number of children.	Accommodation in Special Schools.
		March 31st, 1923.
1. Blind children..	5,401	3,787
2. Deaf children..	5,491	4,582
3. Mentally defective children ..	29,278	16,392
4. Physically defective children:—		
(i) Non-tubercular crippled children ..	34,591	Hospital schools 2,759 Cripple schools 6,386
(ii) Delicate children ..	49,358	Open-air schools 4,690

It will be readily understood that it is extremely difficult to give really accurate figures of the number of defective children. The whole matter is considered in detail in Section VI. of the Report of the Board's Chief Medical Officer for 1923.

REDLANDS HOSPITAL FOR WOMEN, GLASGOW.—

This hospital, formerly known as the Glasgow Women's Private Hospital, which was opened last month by the Viscountess Rhondda, is the only hospital of its kind in the West of Scotland. It is situated in the West End of Glasgow and is staffed by medical women with the exception of four honorary consulting officers. The hospital contains 50 beds and the patients all contribute to their maintenance. In the wards they pay 30s. weekly, but receive free medical and surgical attendance. There are rooms with four beds and two beds, and also single rooms. There is also a well-equipped maternity department, having both ward and single-room accommodation, with an up-to-date labour room.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, March 16th.

SOCIAL EVENING: at 8.30 P.M.

At 8.30 P.M., Fellows, Members of Sections, and their Friends will be received by the President, Sir St. Clair Thomson.

At 9.30 P.M., Dr. H. Charles Cameron will give an address in the Robert Barnes Hall on John Locke, the Philosopher (1690), on the Upbringing of Children. The Library will be open, and various objects of interest will be exhibited. Music, light refreshments, and cigarettes.

Tuesday, March 17th.

GENERAL MEETING OF FELLOWS: at 5.30 P.M.

PATHOLOGY: at 8.30 P.M.

Annual General Meeting:

Election of Officers and Council for Session 1925-26.

Communications:

A. Piney: (1) The Morphological Factors Concerned in the Incidence of Pernicious Anæmia. (2) The Blood in Rubella.

W. Cramer: On the Relation of Innervation to the Experimental Production of Cancer.

Wednesday, March 18th.

HISTORY OF MEDICINE: at 5 P.M.

Papers:

Prof. J. S. Dobson: On Herophilus of Alexandria.

Mr. C. J. S. Thompson: Some Historic Remedies and Their Origins.

Thursday, March 19th.

DERMATOLOGY: at 5 P.M. (Cases at 4 P.M.)

Cases:

Dr. A. C. Roxburgh: Case for Diagnosis.

Dr. J. M. H. MacLeod: Hemiatrophy of the Face.

Other cases will be shown.

Friday, March 20th.

ELECTRO-THERAPEUTICS: at 8.30 P.M.

Papers:

Dr. Gilbert Scott: A General Survey of Radiation with Special Reference to Treatment of Carcinoma of the Breast by X Rays.

Dr. J. H. Douglas Webster: Results and Problems in Deep Therapy.

ROYAL INSTITUTION, Albemarle-street, W.

TUESDAY, March 17th.—5.15 P.M., Prof. E. N. da C. Andrade:

Evolution of the Scientific Instrument (II.).

THURSDAY.—5.15 P.M., Dr. Leonard Hill: Biological Action of Light (II.).

FRIDAY.—9 P.M., Prof. J. W. McBain: Soaps and the Theory of Colloids.

SATURDAY.—3 P.M., Sir Ernest Rutherford: The Counting of the Atoms (IV.).

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, March 16th.—9 P.M., Sir Bernard Spilsbury:

Wounds and Other Injuries in Their Medico-Legal Aspect (last Lettsomian Lecture).

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

TUESDAY, March 17th.—8.30 P.M., Dr. Nathan Raw:

Three Suggested Grounds for Divorce: (1) Hopeless Insanity; (2) Chronic Inebriety; (3) Sentence of Penal Servitude for Life. Discussion.

TUBERCULOSIS SOCIETY, 1, Upper Montague-street, Russell-square, W.C.

FRIDAY, March 20th.—8 P.M., Dr. W. H. Dickinson: League of Nations Post-Graduate Course.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

THURSDAY, March 19th.—8.15 P.M., A Laboratory Meeting

at the Royal Army Medical College, Grosvenor-road, Millbank, S.W. The following amongst others will give

demonstrations: Dr. Douglas Adams, Dr. A. W. Grace,

Dr. E. Hindle, Dr. J. T. Duncan, Dr. H. B. Newham,

Dr. A. S. Burgess, Colonel Marrian Perry, Dr. H. Seidelin,

Dr. A. C. Stevenson, Dr. J. Gordon Thomson,

Dr. C. M. Wenyon, Mr. A. L. Sheather, and Prof.

Warrington Yorke.

LECTURES, ADDRESSES, DEMONSTRATIONS. &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, March 16th to March 21st.—BARNES HALL,

Royal Society of Medicine. A Discussion on Post-

Graduate Teaching in London will take place on

Wednesday, March 18th, at 6 P.M., Sir Arbuthnot Lane,

Bt. (President of the Fellowship of Medicine), will

preside. All members of medical profession are invited

to attend and to give their criticisms of the existing

arrangements and suggestions for improvement.—

CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd-street,

W.C. Lecture-demonstrations in Diseases of the Eye.

Daily in the afternoons.—CHELSEA HOSPITAL FOR

WOMEN. Special Course in Gynaecology. Lectures,

Demonstrations, Operations, &c.—HOSPITAL FOR CONSUMPTION, Brompton. Special Course in all Departments of Diseases of the Lungs, Phthisis, Heart and Treatment by Artificial Pneumothorax.—NORTH-EASTERN FEVER HOSPITAL, St. Ann's-road, N., Wednesday and Saturday at 11 A.M., Demonstrations on the Diagnosis and Treatment of the Acute Infectious Diseases will be given by Dr. Frederic Thomson.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Special Course in Medicine, Surgery, and Gynecology. Lecture-demonstrations will be given in the Wards and Out-patient Departments.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, March 16th.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2 P.M., Mr. Addison: Surgical Wards. 2.30 P.M., Dr. Saunders: Medical Wards.

TUESDAY.—11 A.M., Mr. Endean: Venereal Diseases. 12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Mr. Tyrell Gray: Surgical Wards.

WEDNESDAY.—11 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Burnford: Medical Wards. 2 P.M., Dr. Owen: Medical Out-patients.

THURSDAY.—11 A.M., Sir Henry Simson: Gynecological Wards. 2 P.M., Mr. MacDonald: Genito-Urinary Dept. 2 P.M., Mr. Bishop Harman: Eye Dept.

FRIDAY.—11 A.M., Dr. McDougal: Medical Electricity. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

SATURDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M. In-patients, Out-patients, Operations, Special Departments.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

TUESDAY, March 17th.—4.30 P.M., Dr. F. G. Crookshank: Rheumatoid and Osteoid Arthritis.

FRIDAY.—4.30 P.M., Mr. E. Gillespie: Some Uses of Orthopaedic Surgery.

Daily: Medical and Surgical Clinics, Clinics in the various Special Departments, Surgical Operations, &c.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: FEB.—MARCH, 1925.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, March 16th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Syphilis of the Nervous System (2): Dr. Adie.

TUESDAY, March 17th.—2 P.M., Out-patient Clinic: Dr. Adie. 3.30 P.M., Disseminated Sclerosis: Dr. Birley.

THURSDAY, March 19th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Friedreich's Ataxia: Dr. Gordon Holmes.

FRIDAY, March 20th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Demonstration of Physical Exercises in Exercise Room: Mr. Elmquist.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE PATHOLOGY OF THE NERVOUS SYSTEM.

THURSDAY, March 19th.—12 noon, The Neuroglia: Dr. J. G. Greenfield.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM.

MONDAY, March 16th.—12 noon, Cerebral Cortex and Cerebral Localisation: Dr. Hinds Howell.

A COURSE OF CLINICAL DEMONSTRATIONS, chiefly on METHODS OF EXAMINATION OF THE NERVOUS SYSTEM, is held in the Wards at 10 A.M. on Tuesdays and Fridays by Dr. H. J. Macbride.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE NEUROLOGY OF THE EYES.

WEDNESDAY, March 18th.—3.30 P.M., The Oculomotor Nerves: Mr. Leslie Paton.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced. Full particulars on application to

J. G. GREENFIELD, Dean of Medical School

HOSPITAL FOR SICK CHILDREN, Gt. Ormond-st., W.C. THURSDAY, March 19th.—4 P.M., Dr. Shires: X Ray Diagnosis of Diseases of the Chest.

ST. JOHN'S HOSPITAL, 49, Leicester-square, W.C. TUESDAY, March 17th.—5 P.M., Dr. A. C. Roxburgh: Scleroderma. Neurofibromatosis.

ST. MARY'S HOSPITALS, Manchester. FRIDAY, March 20th.—4.30 P.M., Post-Graduate Lecture (at Whitworth-street, West Branch), Lr. J. Bride: Visit to the Obstetric Wards.

MANCHESTER ROYAL INFIRMARY. TUESDAY, March 17th.—4.15 P.M., Mr. J. Morley: Oesophageal Diverticula and Cardiospasm.

FRIDAY.—4.15 P.M., Dr. E. B. Leech and Mr. J. Howson Ray: Clinical Cases.

ST. ANDREWS INSTITUTE FOR CLINICAL RESEARCH. TUESDAY, March 17th.—4 P.M., Prof. Murray Lyon: Diuretics. Discussion to be opened by Prof. Charteris and Dr. Maitland Ramsay.

CHADWICK PUBLIC LECTURES. FRIDAY, March 20th.—7 P.M. (at University College, Cardiff), Dr. W. M. Feldman: Antenatal Child Physiology and Hygiene.

SATURDAY.—3 P.M., Postnatal Child Physiology and Hygiene.

THE PEOPLE'S LEAGUE OF HEALTH.

Lectures on What We Should Eat and Why, at the Medical Society of London, 11, Chandos-street, W.

WEDNESDAY, March 18th.—6 P.M., Dr. M. J. Rowlands: Feeding and Breeding of Stock.

Appointments.

BARR, WILLIAM, M.D., Ch.B. Glasg., D.Sc.P.H., has been appointed Medical Officer of Health to the County Borough of Rotherham.

BEALE, PEYTON T. B., F.R.C.S. Eng., Consulting Surgeon to King's College Hospital.

GAMLEN, H. E., M.B., B.S., D.P.H. Durh., Honorary Physician in charge of the Electrical and Massage Departments, Royal Victoria Infirmary, Newcastle-upon-Tyne.

LAMBERT, MARJORIE A. M., M.R.C.S., L.R.C.P. Lond., House Surgeon to the New Sussex Hospital for Women and Children, Brighton.

MOORE, F. CRAVEN, M.D., M.Sc. Manch., F.R.C.P. Lond., to the Chair of Systematic Medicine in the University of Manchester.

MYLES, D. M.B., Ch.B. St. And., Medical Officer, Forfar Parish Council.

Freemasons Hospital and Nursing Home: BOX, CHARLES R., M.D., B.S. Lond., and BEAUMONT, G. E., M.D. Oxon., Physicians; CHRISTOPHERSON, J. B., M.B., B.Ch. Camb., Tropical Diseases; EVANS, ARTHUR, F.R.C.S., M.D., M.S. Lond., GRAY, H. TYRELL, F.R.C.S. Eng., FITZWILLIAMS, DUNCAN C. L., F.R.C.S. Eng., Surgeons; BONNEY, VICTOR, F.R.C.S. Eng., RIVETT, L. CARNAC, F.R.C.S. Eng., Gynecologists; MACDONALD, S. G., F.R.C.S. Eng., Genito-Urinary; FRENCH, J. GAY, F.R.C.S. Eng., NEILSON, D. F. A., F.R.C.S. Eng., Throat and Ear; MAYOU, M. S., F.R.C.S. Eng., Ophthalmic; BATTEN, H. E., F.R.C.S. Eng., Orthopaedic; BERRY, HERBERT MARTIN, M.D. Liverp., Radiologist; DOBSON, L. C., M.D. Lond., Electro-Therapeutist; CHAMBERS, HERBERT, M.R.C.S., L.R.C.P. Lond., GANDY, ERIC W., M.R.C.S., L.R.C.P. Lond., IRONSIDE, R. W., B.Ch. Camb., PHILLIPS, H. R., M.D., Ch.B. Edin., Anaesthetists; HARRIS, H. E., Surgeon-Dentist.

Metropolitan Asylums Board: MCCARTNEY, J. E., M.D., Ch.B. Edin., Director of the Board's Pathological Services; WHITE, R. G., M.B., Ch.B. Glasg., Director of the Antitoxin Establishment.

Vacancies.

For further information refer to the advertisement columns.

Albert Dock Hospital, Connaught-road, E.—H.S.'s at rate of £110. Barnstaple, North Devon Infirmary.—H.S. at rate of £150.

Bath, Royal United Hospital.—Hon. Asst. S.

Belfast, Mater Infirmorum Hospital.—Hon. Asst. Gynecologist. Belfast, Ulster Hospital for Children and Women, Templemore Avenue.—Hon. Asst. P.

Belgrave Hospital for Children, Clapham-road, S.W.—H.P., H.S., and Asst. H.P. at rate of £100.

Birmingham, Queen's Hospital.—Third Phys. £50.

Boole Borough Hospital.—Hon. S.

Bradford Municipal General Hospital, St. Luke's.—H.P. and H.S. at rate of £200 each.

Brighton, New Sussex Hospital, Windlesham-road.—Hon. Asst. P. and Temp. Asst. S.

Bristol University.—Lecturer in Pathology.

British Guiana.—Asst. M.O.H. £500.

British Hospital for Mental Disorders, &c., 72, Camden-road, N.W. Hon. P.

Bromley Borough.—M.O.H. £800.

Burton-on-Trent Infirmary.—H.S. £150.

Buxton, Derbyshire, Devonshire Hospital.—Asst. H.P. at rate of £150.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—H.S. Also Jun. H.S. at rate of £100 and £50 respectively.

Coventry and Warwickshire Hospital.—Res. H.P. £125.

Doncaster Royal Infirmary and Dispensary.—Hon. Ophth. S.

Dover, Royal Victoria Hospital.—H.S. £180.

Dreadnought Hospital, Greenwich.—H.P. and H.S. Each at rate of £110.

Elizabeth Garrett Anderson Hospital, 144, Euston-road, N.W.—Clin. Asst. £1 1s. per session.

Evelina Hospital for Children, Southwark, S.E.—H.S. at rate of £120. Also Anaesthetist. 25 guineas.

Exeter, Royal Devon and Exeter Hospital.—H.P. at rate of £150.

Federated Malay States.—Research Studentship in Tropical Medicine. £700.

Folkestone, Royal Victoria Hospital.—R.M.O. at rate of £150.

Glasgow, Consumption Sanatoria of Scotland, Bridge of Weir.—Res. M.O. £200—£250.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—R.M.O. and H.P. at rate of £150 and £100 respectively.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S., H.P., and Asst. Cas. O. Each at rate of £50.

Leamington Spa, Warneford General Hospital.—Hon. Asst. P. and Hon. Asst. S.

Leeds City.—Asst. M.O.H. for Maternity and Child Welfare. £600.

Lichfield County Mental Hospital, Burnthwood.—Sen. Asst. M.O. £750.

Liverpool Sanatorium, Delamere Forest, Frodsham.—Asst. M.O. £200.

London Homœopathic Hospital, Great Ormond-street, W.C.—Pathologist. £200.
 London Hospital, E.—First Asst. to Surgical Firm. £400.
 London Lock Hospital, 91, Dean-street, W.—Surg. Reg. £100.
 London Lock Hospital, 233, Harrow-road, W.—Temp. Hon. S. to Out-patients.
 Maidstone, Kent County Mental Hospital.—Asst. M.O. £300.
 Maidstone, West Kent General Hospital.—H.S. at rate of £220.
 Manchester, St. Mary's Hospitals.—Two H.S.'s. Each at rate of £50.
 Manchester University.—Lecturer in Morbid Anatomy and Histology. £500.
 Metropolitan Hospital, Kingsland-road, E.—S. for Diseases of Nose, Throat, and Ear.
 Miller General Hospital for South-East London, Greenwich-road, S.E.—H.P. £125.
 National Hospital for Diseases of the Heart, Westmoreland-street, W.—Res. M.O. at rate of £150. Also Out-patient M.O. at rate of £125.
 Newcastle-upon-Tyne, Royal Victoria Infirmary.—Med. Reg. at rate of £50. Also Hon. Asst. to Electrical and Massage Depts.
 Nottingham Children's Hospital.—Res. H.S. at rate of £150.
 Plymouth, South Devon and East Cornwall Hospital.—H.P. and Asst. H.S. Each at rate of £50.
 Putney Hospital, Lower Common, Putney, S.W.—R.M.O. £150.
 Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—R.M.O. £200. Also Two H.P.'s and Cas. H.S. Each at rate of £100.
 Redhill, Surrey, Royal Earlswood Institution.—Jun. Asst. M.O. at rate of £250.
 Royal Chest Hospital, City-road, E.C.—Phys. £50.
 St. Pancras Dispensary, 39, Oakley-square, N.W.—Hon. Phys. £100.
 Sheffield Royal Hospital.—Hon. Radiologist.
 South London Hospital for Women, South Side, Clapham Common, S.W.—H.P. and Three H.S.'s in each case at rate of £50.
 Sudan Medical Service.—Two Medical Inspectors. £E.720.
 Sutton, Surrey, Downs Hospital for Children.—Second Asst. M.O. £550.
 Suva, Fiji.—Port M.O. and Bacteriologist, &c. £750.
 Wandsworth Common, Springfield Mental Hospital.—Asst. M.O. £400.
 West London Hospital, Hammersmith-road, W.—H.P. and Two H.S.'s. Each at rate of £100.
 The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Coxhoe, Durham; and Brigstock, Northampton.

Births, Marriages, and Deaths.

BIRTHS.

BOND.—On March 5th, at Bulford Camp, the wife of Major A. H. Bond, R.A.M.C., of a son.
 CHAPMAN.—On March 1st, at Marine House, Bridlington, the wife of P. D. H. Chapman, M.B., of a daughter.
 JACKSON.—On March 6th, at Coombe House, Wallington, Surrey, the wife of G. Maudsley Jackson, M.B., B.S., of a son.
 SIDEBOTHAM.—On March 2nd, at Raleigh House, Ottery St. Mary, the wife of Dr. F. N. Sidebotham, of a daughter.

MARRIAGES.

MANN—HOWELL.—On March 7th, at Christ Church, Hendon, James Wallace Mann, M.B., Ch.B., to Margaret Olwen Howell, M.B., B.S., second daughter of the late John Howell and Mrs. Howell, Llanelli.

DEATHS.

BROWNE.—On March 7th, at Minto, Esher, Samuel Browne, M.D., late R.N., aged 74.
 BURROWS.—On March 8th, at Devonshire House, Southsea, Lucy Mary Elizabeth, the beloved wife of Harold Burrows.
 CLELAND.—On March 5th, at Moorcroft, Lidsing, Chatham, John Cleland, M.D., F.R.S., &c., Emeritus Professor of Anatomy, University of Glasgow, in his 90th year.
 COMPTON.—On March 2nd, at midnight, Thomas Armetriding Compton, M.D., Trinity Coll., Dublin, B.A. Camb., of Journey's End, Parkstone, aged 87.
 KER.—On March 4th, at the City Hospital, Edinburgh, of influenza pneumonia, Claude Buchanan Ker, M.D., F.R.C.P. Edin., Medical Superintendent, aged 57.
 KNIGHT.—On March 5th, at Bolton-le-Sands, Alexander Angus Halley Knight, M.D.
 MOORE.—On March 7th, Colonel E. J. Moore, C.B., V.D., M.B., B.Ch. Ox., of Park End, Blackheath Park, aged 62.
 ORMEROD.—On March 5th, Joseph Ardenne Ormerod, M.D., F.R.C.P.
 PEARSON.—On March 4th, at a nursing home, Cheltenham, John Douglas Pearson, M.R.C.S., L.R.C.P.
 WHITELEY.—On March 7th, Daniel Flockton Whiteley, M.R.C.S., L.R.C.P. Lond., of Coleherne Court, S.W.
 N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

GREENOCK INFIRMARY.—It is proposed to establish an auxiliary hospital in the Inverkip Valley to relieve the pressure upon the infirmary, and Mr. Matthew Rankin and Miss Rankin are giving £20,000 for the purpose in memory of their brother, Mr. John F. Rankin, who died recently. The new building is to be so arranged that it can readily be extended.

Notes, Comments, and Abstracts.

THE METHOD OF TRIAL IN MATE SELECTION.

THE majority of anthropologists have maintained that primitive society was committed to the system of group marriage and promiscuity, in which sexual selection could play but a trivial part, though Darwin raised his voice in protest, asking how humanity could have progressed without selective mating in the earlier phases. But his views and those of Westermarck and others were overshadowed by the preponderating opinions of many authorities. It was to re-establish those views that Prof. Malinowski was concerned in a recent address to the Eugenics Education Society. He took as his theme the marriage customs of a tribe of Melanesian islanders from the north-west of New Guinea, where he had been engaged in field-work. The peoples were among those hitherto regarded as classical examples of a system of promiscuity and group marriage, but he had satisfied himself that certain institutions, which on a superficial observation appeared to belong to this system, were in fact of a different nature. Among these people immature sexual gambols begin in early childhood and are regarded by the community with indifference as "natural," the only restraint, which is strictly observed, being against incest or exogamy. At puberty the childish dalliances give place to more serious and passionate attachments, but these are not associated immediately with marriage and permanent relations. The sexual approach shows greater variety in manifestation as age advances, romantic and æsthetic elements come into prominence, and there is a definite attempt to achieve possession of the beloved, by work, by magic, or other means. During this time the couples can sleep together freely in certain houses specially set apart for them, and this is the phenomenon which has been interpreted as the institution of group marriage. When closely scrutinised it is found to be of a different nature. There is no promiscuity in these houses; the couples who frequent them remain faithful to each other and a strict decorum is observed. The houses form, in fact, a provision for the method of trial in the selection of the mate, while strict convention demands that unmarried couples shall not live together in any other sense—to eat with a girl before marriage is as shocking to these Melanesian people as their methods for testing compatibility are to us. Sooner or later a lasting intrigue becomes known among the tribe to have occurred between a couple and this is taken as an indication of intended marriage, while on the whole the ensuing unions are permanent and satisfactory. The final choice is based on a mutual appreciation of the character and personality of the mate, and so the principle of selective breeding is clearly subserved. One obvious question refers to the number of illegitimate children, and this is answered by the curious fact that babies are hardly ever born as a result of the early intrigues, while "fatherless children" are regarded as reprehensible results on the part of the mothers; but exactly how their incidence is prevented is not clear. The tribe, then, which has no realisation of the physiological basis of fatherhood, yet sees the sociological need of two parents, and the institution of the family is firmly established by custom and legality.

Prof. Malinowski's investigations raise many problems of interest. Civilisation is still concerned with the difficulties presented by human nature in the attempt to stabilise family life and monogamy. The method adopted to this end by recent European culture differs fundamentally from that of these Melanesians, yet the end desired is the same and seems to be about equally achieved by either route. Both methods are attended by certain physical and psychopathological results; we are accustomed to regard such free expression of the sexual instinct as a drain on the strength of the organism, and modern psychology has preached from the housetops the baleful results of repression. An interesting sidelight on this was thrown by Prof. Malinowski's statement that hysteria and mental disease are far more commonly met with in tribes with strict sexual limitations than among those with extensive sexual liberty. It seems certain that a psychological appreciation of the values and characteristics of the mate is the only possible basis for permanent partnership. Some doubt may be thrown on the ability of such primitive peoples as these Melanesians to experience such a conscious appreciation as we should understand by these terms, but they are probably able, when free of the distorting effect of unexpressed emotional tension, to find their psychological affinity or complement in a subconscious or instinctive fashion and thus to fulfil the demands of natural selection. It is interesting to note that these people have long been in contact with European

culture and yet have been affected by it less than any. Missionaries have laboured in vain to modify their customs and their clothes—or lack of clothes. Now all that elaboration of æsthetic, moral and intellectual development which we associate with cultured humanity seems to have resulted psychologically from the process of inhibition. It may be suggested that the method of free expression practised by these people is to be correlated with the fact that they have proved so resistant to Western influence. Their method is satisfactory from the biological point of view, the desired ends are attained, but they are bound by it to a condition of "nature," and the gateway to all that wealth of human experience which flows from diversion of instinctive impulse into alternative channels is to them forever closed. It seems probable that the two paths of expression and repression are two extremes, each attended with certain penalties, and that future generations will find some "middle way" between the restrictions of Mrs. Grundy and the licence of the South Sea Islander.

NATIONAL BABY WEEK COUNCIL.

THE annual general meeting of the National Baby Week Council was held at 117, Piccadilly, London, W., on March 4th, when a satisfactory account of the year's work was given by Dr. Eric Pritchard, chairman of the Executive Committee. Sir Arthur Newsholme, who presided, congratulated the Council on their work of saving child life throughout the country, and said that the good done in forming public opinion could not be over-estimated under a system of democratic government. The results of the efforts made to preserve infant life during the past 20 years had been marvellous, and since the end of the last century the death-rate had been halved. This could be explained by a large number of factors, among which publicity and education had been the most essential. Infantile diarrhoea had become a rare disease in London, and it was even difficult to get hold of well-marked clinical cases for demonstration to students.

An amendment to the constitution of the National Baby Week Council was agreed to, providing for membership of local authorities and voluntary bodies doing continuous maternity and child welfare propaganda.

I. R. J. A. Hadfield gave an address on the

Formation of Character: A Problem of Child Psychology.

After pointing out that some of the abnormalities which occurred late in life were directly derived from, and were themselves reproductions of, morbid infantile states of mind, I. R. Hadfield went on to show how the character of the adult depended upon the earlier experience and training of the child. The first years of life, he said, were characterised by a feeling of dependence, followed by the development of self-will and the desire for self-gratification. In the third and fourth year came self-knowledge and self-consciousness, the development of the moral sense, and of the will. It was important that all these phases of life should have their proper and normal development. All these impulses could be dealt with in different ways; they might be indulged or repressed and crushed, but if they were crushed disorders might develop in later life. If they were well directed, the result would be the full and true development of character. These tendencies should be directed towards some ideal. The child whose dependence was over-indulged would never "grow up," and would never be prepared to face the responsibilities of life. On the other hand, there might be a danger of mistaking what seemed to be over-affection for the mother for real starving of affection—the mother not being sufficiently responsive. The end-result in later life was often hysteria. If the attempt was made to make a man of a child at the age of 1½, the result would probably be the production of a coward. If the impulse of gratification were crushed the result in after life might be sense perversions, while if the tendency was controlled, guided, and directed the formation of a strong character would result. The proper guidance of self-will was of great importance, for tremendous harm was done by crushing the impulsive tendencies which were engendered by it. The will of the child of 3 or 4 years was merely the reproduction of the parental will and authority exercised at the age of 1 and 2. The child's choice should be developed, it should be taught how to do things, if it showed tendencies to do them, and in this connexion he, Dr. Hadfield, thought that the age of 2 years was not too early to teach a child to strike a match and light a fire, if it wished to do so. It might seem paradoxical, but if the child wanted to do "naughty" things it had better be taught how to do them properly. A factor of enormous importance was the single atmosphere in child training. The greatest damage could be done to the child's life if it were treated differently by different people, or if the father and mother were not in agreement in regard to control. The child whose parents did not always deal with it in the

same way for the same fault was led to the attitude of the criminal type who in committing a crime knew he would get no choice, if caught, and so just "chanced his luck."

COLONIAL HEALTH REPORTS.

BECHUANALAND PROTECTORATE.

THE territory of the Protectorate is bounded on the south and east by the Union of South Africa, on the north-east by Southern Rhodesia, on the north by the Zambesi and Chobe (Linyanti) Rivers, and on the west by the territory of South-West Africa. It has not been surveyed as a whole, but its area is estimated at 275,000 square miles. Its mean altitude is about 3300 feet. The population at the census of 1921 was 152,983, including 1743 whites. The health conditions throughout the territory for the year ended March 31st, 1924, are stated, in the annual report just to hand, to have been on the whole satisfactory. As in the past, malaria and its sequelæ head the list of prevalent diseases. During the early months of the year there were several outbreaks of the disease in the northern districts. These, though of the benign tertian form, were of more than usual severity in character: but they were not sufficiently widespread or severe to affect the economic position either through disablement or direct or indirect mortality. As against this, the prevalence of the disease throughout the southern areas was occasional only, and its character uniformly mild. Respiratory troubles came next in order, but these, though figuring largely in the list, were of the light and non-dangerous variety. Of severe intestinal ailments, 16 cases of dysentery had to be recorded in the year, with 1 death. All these occurred in the northern part of the territory. There was an epidemic of measles in the village of Gaberones and at other isolated posts in the neighbourhood, as well as at Ramoutsa, where the mortality was high. There were 2 cases of scarlet fever at Gaberones camp. The portion of the country inhabited by the greater number of both Europeans and natives is adjacent to the only line of railway which passes through the eastern side of the territory for a distance of 403 miles; the average altitude of the stations and sidings along this section of the line is 3418 feet.

BRITISH HONDURAS.

This colony, in Central America, on the Atlantic side of the mainland, has an area of about 8598 square miles. The country is well watered, and its rivers, which are many, provide the chief means of communication. The climate, for a tropical area, is naturally very healthy, and in Belize (the capital), where the trade winds blow, pleasant for most of the year. The estimated population on Dec. 31st, 1923, was 46,527. The report for 1923 states that the general health of the colony during the year was exceptionally good; 112 cases of malaria of all types were treated in the Belize Hospital without any deaths, and 134 cases were treated in district hospitals with 4 deaths. The returns of deaths for the whole colony show 32 deaths certified by registered medical practitioners from malaria. On referring to the cause of deaths in cases not certified by registered medical practitioners, there is naturally considerable doubt as to the diagnosis, but it is probable that about 150 were due to malaria. As to the actual prevalence of malaria there are no statistics, but it is probable that malaria is the cause of a great majority of absences from work and invalidity. Sixteen cases of amoebic dysentery and 3 cases of bacillary dysentery were treated in Belize Hospital with one death; 39 cases of both types were treated in district hospitals with one death. Ten deaths were certified by registered medical practitioners as due to dysentery. There were 8 certified deaths from tetanus. Thirty-one cases of pulmonary tuberculosis, with 16 deaths, were treated in Belize Hospital, and 21 cases, with 5 deaths, in the district hospitals; 41 certified deaths from this disease were also registered. It is impossible to estimate the number of uncertified deaths from this cause, but they are undoubtedly very many. Filariasis is unknown in the colony, and plague has never occurred. Small-pox has never reached the colony, and the alastrim of Jamaica has also not appeared. The passengers from Jamaica are subject to medical supervision for 14 days from date of departure unless they are able to produce satisfactory proof of recent vaccination. Vaccination here (primary) is carried out fairly well. The number of births registered during the year was 1764, and the number of deaths 954, the birth-rate working out at 37.91 per 1000 of the population, and the death-rate at 20.5 per 1000. There was a decrease in the number of infant deaths. The highest rainfall registered in 1923 was at Punta Gorda in the Toledo district, which had a total of 149.85 inches. The lowest was at Corozal, where the total was only 25.05 inches. The hottest days were Oct. 17th and 18th, on which the thermometer registered 91.5°F., and the coldest day Nov. 16th, when it registered 61.5°F.

LEGISLATION AND SMOKE ABATEMENT.

A Chadwick public lecture was delivered on March 9th at the Inner Temple Hall by Lord Newton, who spoke on the necessity for legislation with regard to smoke abatement. Sir William J. Collins was in the chair. After describing the waste and damage to health and property caused by smoke, Lord Newton said that it was surprising no effective steps were taken to deal with this national nuisance. Smoke nuisances were usually dealt with under the Public Health Act of 1875, but owing to its ineffectiveness various towns had obtained local Acts. The difficulties attending the enforcement of the 1875 Acts as regards smoke had resulted in complete inaction in many districts, local authorities having become apathetic. This attitude, however, was largely due to the apathy of the central authority. No Government had shown, he said, until quite recently, the slightest interest in smoke abatement, and the old Local Government Board consistently declined to put any pressure on local authorities. It was not until 1914 that, as the result of much educational work by private individuals and societies, a departmental committee was appointed. The activities of this committee were suspended during the war, but its work was resumed in January, 1920, and after an exhaustive inquiry the first report was issued in December, 1921. This report, after dealing with the deficiencies of the present law, made certain recommendations, none of which had ever met with any opposition, but which hitherto had been completely ignored.

Amongst the recommendations were the following (1) Power to the Minister of Health to compel a defaulting authority to act. (2) An amendment to the law providing a general legal obligation on manufacturers to use the best practicable means for avoiding pollution instead of prohibiting absolutely the emission of "black" smoke. (3) Power to the Minister of Health to fix standards, as in the case of the Alkali Acts. (4) The duty of enforcing the law to be transferred from the local sanitary authorities (1800 in number) to the county councils and county boroughs. (5) The imposition of larger fines than at present. All recommendations were made on the assumption that questions of cost must be taken into account in determining what was practicable. With regard to domestic smoke, it was recommended that the central housing authority should not sanction any housing scheme submitted by a local authority unless provision was made in the plans for the adoption of smokeless methods, granting that the adoption of such methods was considered by the central authority to be practicable.

Since the production of the departmental committee's report, the lecturer continued, three Bills had been introduced by three successive Governments, but in each case they failed to embody the main recommendations of the committee, and were introduced at so late a period of the session that there was obviously no serious intention of passing them. The present Minister of Health, having been approached on the subject, had intimated that there was no time to pass a Bill this year, but that he would endeavour to introduce one early next year. Lord Newton submitted that if it was seriously desired to get rid of the smoke nuisance fresh legislation was imperative. No improvement in the situation would reasonably be expected until the Ministry of Health intervened and insisted upon a more efficient and uniform administration. "It is difficult to understand," he concluded, "why this Ministry was ever created if it is not to concern itself with a matter which affects the health, economy, and general amenity of life of the vast majority of the population."

COÖPERATION BETWEEN DOCTOR AND DENTIST.

IN 1921, as the result of a Departmental Committee of the Privy Council, a new Dentists Act was passed, which provided that no unregistered person should henceforth be able to practise dentistry. Under this Act a number of hitherto unrecognised practitioners who had vested interests became entitled to registration on complying with certain requirements. The Dental Board of the United Kingdom was established, and a large degree of autonomy was given to the dental profession. It was not to be expected that the 6000 qualified dentists then registered would appreciate the dilution of their body by the addition of some 8000 names. But the struggle of the unqualified men to obtain recognition, to secure registration, and to achieve some means of self-government had been arduous, the opportunity of making a start on the road towards the creation of an autonomous and respected profession was wisely seized, and the British Dental Association strongly supported the Government Bill which ultimately became law. Now dentists admitted under the 1921 Act range from men who have passed through the whole curriculum but failed in their final, and for want of means have

not qualified, through men who have had a really good apprenticeship and know a great deal about the practical side of their work, down to men whose early experience was gained at the expense of their patients. Even the last-named class have often acquired sound judgment as well as mechanical skill in the course of the years of practice which led to their inclusion on the Register. A letter from the Registrar of the General Council of Medical Education and Registration of the United Kingdom, which was published in THE LANCET of Feb. 28th, implies that doubt has arisen as to the propriety of coöperation between medical men and dentists admitted under the Act. He points out that doctors are entirely at liberty to give an anæsthetic for any person whose name appears in the Dental Register. We would be inclined to go further and to contend that refusal to coöperate could hardly be justified on general grounds. A practitioner called upon to administer an anæsthetic for any individual operator, however well qualified, whom he believed to be unskilful would be faced with a difficult problem; but any invidious distinction between those who have achieved membership of an honourable profession by examination and those who have been admitted to its privileges on other grounds is unseemly, and is likely to injure both professions in the eyes of the public.

A USEFUL WARNING.

To the Editor of THE LANCET.

SIR,—Last week our out-patient superintendent saw a man hanging about the department and speaking to patients. Wanting to know his business he pretended to be a patient, and limped past him, whereupon this man gave him a card with the name and address: "V. J. Vowler, Claims Assessor, 11, Ludgate Hill, E.C. 4," on it.

I wrote to Mr. Vowler asking for his explanation, and the enclosed correspondence has passed.

I think this method of getting business so objectionable that I feel all hospitals should be warned.

I am, Sir, yours faithfully,

London Hospital, E., March 6th, 1925.

KNUTSFORD.

[ENCLOSURES.]

(1)

To the Viscount Knutsford.

Kneesworth Hall, Royston, Herts.

MY LORD,—I am in receipt of your communication of the 26th ultimo in which you complain that your out-patient superintendent whilst pretending to be a hospital patient with a bad limp was given a card of mine.

I may say at once that I am not the person who it is stated gave your superintendent my card and I know nothing whatever about the matter, and the suggested indiscriminate and promiscuous use of the card by the individual in question was entirely without my knowledge or sanction and would not be countenanced by me.

At the moment I cannot make up my mind whose conduct it is to be deprecated most, your superintendent's for masquerading and assuming the rôle of an injured man or the other individual, but I do not know that I should view with great discrimination any complaint emanating from a gentleman whose zeal can carry him so far as to pretend to have an affliction which in reality he is fortunate enough to escape.

I am, My Lord, Your Obedient Servant,
V. J. VOWLER.

11, Ludgate Hill, London, E.C. 4, March 2nd, 1925.

(2)

SIR,—You will not find it easy to get anyone to believe that this man was touting for business for you actuated by mere philanthropy.

Do you suggest that he spent his own money in getting your advertisement cards printed, and gave his own time attending the out-patient department of the London Hospital without remuneration direct, or by commission?

Find some innocent marine, and tell him that story. Nobody else would believe it.

Yours faithfully,

KNUTSFORD.

MINISTRY OF HEALTH: CIVIL SERVICE BONUS.

IN a circular (No. 567) addressed to local authorities, the Minister of Health states that the Civil Service bonus, as reviewed on March 1st, has been fixed on the basis of an average cost of living figure of 80—that is, on the same basis as obtained during the six months commencing March 1st, 1924. In so far as insurability under the National Health and Unemployment Insurance Acts of officers employed otherwise than by way of manual labour, and in receipt of bonus on the Civil Service scale, is dependent upon the rate of their remuneration, the question of insurance should be determined until further notice with reference to the basic rate of remuneration, plus the bonus on such remuneration applicable from time to time. Officers of the classes concerned whose rate of remuneration with bonus based on an average cost of living figure of 80 will not exceed £250 a year are thus treated as insurable from March 1st. A "Ready Reckoner" for use in connexion with the bonus scheme has been prepared by the Treasury.

A PECULIAR CASE OF "ALBINISM."

IN THE LANCET of Nov. 15th, 1924, p. 1048, reference was made to a report in *Man* on the so-called white Indians of Panama, and in the current issue of the same journal Mr. F. W. H. Migeod states that there are places in Africa where there is a local tendency to albinism, and infers from certain evidence that the condition has nothing to do with intermixture of European blood. He states also that he has never seen an elderly adult case of albinism; all have been in children or young men. He narrates the case of a soldier, a native of the Gold Coast, Northern Territories Colony, who fell sick, and when, after a long time, he returned to duty he had become entirely white. The black pigmentation had disappeared, except for some mottling. He was in this state when Mr. Migeod last saw him, but this was in 1916. The natives in out-of-the-way places on the Gold Coast account for albinism by saying that the mother when pregnant saw a white man, and, owing to the shock, brought forth a white child, which appears to be a charitable interpretation.

SUMBUL.

WE have received from Messrs. Ralph L. Fuller and Co., of 21, Harp-lane, London, E.C., samples of Russian musk-root more accurately known as sumbul and sometimes called spikenard. They are of interest as showing that the drug, which has always enjoyed some measure of popularity, is again available for British doctors, for during the past eight years the isolated position of Russia has led to its practical disappearance from our markets. Sumbul has been used as a substitute for musk, which it much resembles in odour, while its medicinal properties, due to a resin and an essential oil, are held to be the same as those of asafoetida. It has had a place in the British Pharmacopoeia, but it was well known in Russia many years before it received any recognition in this country. However, as far back as 1850 we find the famous Dr. Robert Bentley Todd, F.R.S., prescribing sumbul in a case of epilepsy under his care at King's College Hospital, when he explained that the root had been brought to his notice by Mr. Savory of Bond-street, who had experienced difficulties in getting genuine supplies from Russia. Messrs. Fuller and Co. inform us that they have secured and warehoused a quantity sufficient to supply the requirements of the trade, and that many pharmaceutical chemists are now notifying their medical clients that tincture of sumbul is again obtainable.

TRAINING AND SUPPLY OF MIDWIVES: GRANTS FROM THE MINISTRY OF HEALTH.

IN 1919 the Board of Education (Midwives' Training) Regulations were issued, under which grants could be made by the Board to recognised residential institutions in aid of the training of intending or practising midwives. As the supervision of the arrangements for securing an adequate supply of midwives is within the province of the Minister of Health, it has been decided that, from April 1st, 1925, the Exchequer grants in aid of the training of midwives shall be made by the Minister of Health and not by the Board of Education, as formerly. The Minister of Health has now issued a Memorandum¹ setting forth the conditions upon which grants from the Exchequer will in future be paid in respect to the training of midwives. The grants, he states, will be paid to recognised residential institutions as in the past, and will be made only in respect of students who intend to practise as midwives or as health visitors or who are already employed as full-time health visitors. Further, as the Central Midwives Board, with the approval of the Minister, have recently revised their rules relating to the training of midwives and have decided to increase the minimum period of training, the new conditions for the grants will provide for the increase required by the extended period of training, which comes into force on May 1st, 1926. With regard to the supply of midwives, a circular (No. 559),² issued by the Ministry to local supervising authorities under the Midwives Acts, states that in rural areas where there are special difficulties in securing and maintaining an adequate supply of trained midwives, the Minister will be prepared to approve of contributions being made by a county council to the County Nursing Association in respect of the provision of trained midwives for service in the area of the council. These contributions will rank for the Exchequer grant of 50 per cent. under the Maternity and Child Welfare Regulations. It is intended that the contributions made by the County Council for the provision of midwives should take the place of any contributions which are or have been made by local authorities towards the cost of the training of midwives.

¹ Memorandum as to the Conditions upon which Grants will be made by the Minister of Health in Aid of the Training of Midwives. Memo 102/M.C.W. London: H.M. Stationery Office. 2d.

² Training and Supply of Midwives. Circular 559. London: H.M. Stationery Office. 1d.

X RAY APPARATUS.

WE have received from Messrs. Watson and Sons a catalogue (No. 68) of X ray apparatus and radium, and on examination it brings home the point that in the future it will be well if the student looks more carefully at the manufacturers' catalogues for descriptions of apparatus, while the writers of text-books might cease giving a third of their space to such technical detail. The present example gives a good list of modern and up-to-date apparatus, although perhaps there are not many novelties. Several useful improvements to Watson's well-known screening stand are shown, while on p. 155 the description of the new Gaiffe-Gallot and Pilon constant tension apparatus for deep X ray therapy is of real interest. The text is accompanied by a useful diagram. It is one of the few catalogues which devotes a good sized section to radium and radium apparatus, and although in so individualised a subject as radium therapy not a great deal of help can be given, many of the illustrations give valuable hints of different workers' technique. The whole catalogue is well printed. Messrs. Watson and Sons (Electro-Medical), Ltd., with whom are incorporated the X ray sections of the General Electric Company, Ltd., the British Thomson-Houston Company, Ltd., are contractors to the Admiralty, War Office, India Office, and many foreign Governments, and the address is Parker-street, Kingsway, W.C.2.

AMBULANCE COMPETITION TESTS.

THREE further additions to the series of folders prepared by Dr. Corbet Fletcher (John Bale, Sons and Danielsson, Ltd., 6d. per folder) for ambulance competition tests have recently been issued. These consist of special articles, hints on competitions, and a series of questions based upon the St. John Ambulance Association's Manual. No. 4, the first of the present series, deals with errors in treatment, No. 5 with the history of competitions and tests, and No. 6 with the preparation of competitions. They should prove valuable to the ambulance student preparing for examination, and to the examiners themselves.

BARBAROUS ENGLISH.

To the Editor of THE LANCET.

SIR,—May I be allowed to enter what I hope will seem a timely protest against the threatened introduction into English medical literature of barbarisms such as "to evaluate" instead of "to value"; "to stress" instead of "to lay stress upon"; "view-point" instead of "point of view"; "such and such diet was fed to such and such an animal" instead of "such and such animal was fed with such and such diet," and the like? I would quote in this connexion the exceedingly apposite remarks of Peter Mark Roget, himself a member of our profession, on the use of such expressions in the beautifully-written introduction to his well-known "Thesaurus of English Words and Phrases."

"Some modern writers, however, have indulged in a habit of arbitrarily fabricating new words and a new-fangled phraseology, without any necessity, and with manifest injury to the purity of the language. This vicious practice, the offspring of indolence or conceit, implies an ignorance or neglect of the riches in which the English language already abounds, and which would have supplied them with words of recognised legitimacy, conveying precisely the same meaning as those they so recklessly coin in the illegal mint of their own fancy."

I enclose my card and remain, Sir,

Yours faithfully,

March 5th, 1925.

M.A., M.D.

M. P.—A certain disability on returning to the erect position after prostatectomy is not unusual. It is possibly due to the thick band of fibrous tissue which forms around the drainage-tube from the bladder to the abdominal wall, which is pulled upon when the patient gets up and begins to walk about. The disability appears to be more pronounced after an operation in two stages than after an enucleation at one, but it is difficult to get reliable evidence on this point.

THE LANCET: SUBSCRIPTION RATES.

Goulstonian Lectures

ON THE STUDY OF

GASTRIC FUNCTION IN HEALTH AND DISEASE.

BY JOHN A. RYLE, M.D., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN AND LECTURER ON MEDICAL PATHOLOGY,
GUY'S HOSPITAL.

LECTURE I.*

THE physiology of the human stomach has acquired so vast a literature since Beaumont's day that the most earnest student could scarcely hope to acquaint himself with all its history, much less to assimilate and to analyse the countless observations and experiments upon which our knowledge has been based. When, therefore, I received the honour of being called to deliver these lectures and decided, not without misgivings, to attempt such a survey as my title suggests, I felt that some explanation of my choice and purpose and of the scope of the undertaking would surely be required of me.

In my choice I was mainly influenced by the nature and the results of certain studies which have claimed my attention during the past five years. For the most part these studies have been of a clinical kind, but it was also my good fortune, at the suggestion of my colleague and teacher, Dr. A. F. Hurst, to be the first to introduce into this country in 1920 the fractional method of gastric analysis devised by Rehfuß and originally described by him in 1914. The investigations with this method in which I have been concerned may be grouped under three headings: (1) an inquiry into normal gastric function (in collaboration with Dr. T. Izod Bennett) based on an examination of 100 healthy men; (2) a collateral and subsequently extended inquiry into the various disturbances of gastric function encountered in the ordinary course of hospital and private practice; and (3) a short series of experiments on myself.

I was further influenced by a belief that something in the nature of a review of recent work on human gastric function might be of value, and even that it might be possible, on the basis of such a review, to formulate a clearer doctrine and a more scientific classification of the dyspepsias than is at present furnished in the text-books of general medicine.

During the past 10 or 15 years medicine may be said to have re-entered upon a physiological phase. Less dependent than formerly upon information acquired in the post-mortem room or available by means of animal experiment, we have turned with a new zest to the more practical study of function, both normal and abnormal, in the living human subject. The physiology of symptoms and the early evidences of perverted activity in one viscus or another are now being widely investigated, and seldom have better conditions obtained for useful collaboration between the physiologist and the physician.

The most important contributions to the study of gastric motility and sensibility include those of Cannon and Carlson in America and of Hurst in this country, while Rehfuß and his collaborators, and Crohn, with the fractional method, have initiated a new line of inquiry into the secretory and chemical phenomena of digestion. In addition, valuable contributions have been made by radiologists and surgeons. It must, however, be admitted that the general effect of all these researches has been rather to diffuse than to crystallise information, and that practical medicine has to some extent suffered in consequence. As so commonly happens, the introduction of new methods has stimulated expectation to march in advance of reason. On the basis of new tests the old error of according to a symptom the dignity of a diagnosis has been revived; we find, for instance,

even in recent literature, hyperchlorhydria and achylia discussed as clinical entities instead of as symptoms of various underlying pathologies. At one period and another radiography and the test-meal have been too highly appraised, and almost inevitably there has resulted a tendency not only to under-rate the importance of clinical observation, but even to disregard clinical data, the very interpretation of which should have been enhanced by the introduction of these methods. Operations have been devised and performed without proper regard for physiological principle, and certain ill-results of surgical interference have been regretted without being studied.

These errors in thought and practice, as is the case with all such errors, are to be traced to lack of accurate knowledge, to lack of correlation of existing information, and to a too frequent exaltation of theory. In the words of John Abercrombie,¹ "The best way of avoiding the errors which have been referred to, will probably be to keep in mind the important principle, that the object of physical science 'is to ascertain the universality of a fact.'" The closer intimacy which now obtains between clinical and physiological research should help to foster this principle.

I shall endeavour, wherever possible and whether dealing with subjective or objective phenomena, to trace the transition from the normal to the abnormal, and to bear in mind the conception so vigorously fostered by the late Sir James Mackenzie² that symptoms are best viewed as expressing disturbances of normal reflex mechanisms. Throughout I shall try to confine myself to considerations of the problem having a practical bearing. To the chemical and bactericidal properties of the gastric juices I shall not refer, for it would take too long and be beyond my scope to discuss them in detail. With structural disease of the stomach, excepting in so far as it is necessarily prominent among the causes of disturbed function, I propose in no wise to concern myself. Nor do I intend to discuss the study of gastric behaviour in animals.

With so much by way of introduction I need only add that the first lecture will deal with the study of the normal gastric responses, and the second and third lectures with the study of the gastric responses to disease.

THE SENSORY FUNCTIONS OF THE STOMACH.

The functions of the stomach may be conveniently reviewed under the three headings—Sensory, Motor, and Secretory. The first and almost the only indication vouchsafed to the individual that these functions are healthy or deranged is the state of his own sensations. In health he is for the most part unaware of his stomach excepting when hunger, satisfaction, or repletion tell him that it is empty, comfortably filled, or over-filled. In disease of many kinds he is reminded of its presence by such symptoms as pain, nausea, vomiting, flatulence, regurgitation, and loss of the desire for food. All of these symptoms may occur in the presence or absence of organic disease of the stomach itself. They therefore indicate derangements of function which may be produced either by local or distal stimuli. It is of the first importance to consider what is the actual significance of these sensations, and such considerations should properly precede a review of the objective evidence. It has long been supposed, and finally established by Hurst³ and others, that the mucosa of the stomach is insensitive to ordinary tactile, thermal, and chemical stimuli, and yet daily experience tells us that the organ possesses a sensibility of its own. Of the sensations which we may associate in whole or in part with the healthy stomach there are only four. These are the gastric elements of hunger, appetite, satisfaction, and repletion. Nausea, it is true, may be induced in an otherwise healthy person by disgusting emotions, and it also accompanies normal pregnancy; I have, however, deemed it better to regard it as a symptom of disordered function.

* Lectures II. and III. will appear in subsequent issues of THE LANCET.

Hunger and Satisfaction.

The most important contribution of the past decade to the study of hunger is to be found in the writings of Carlson,⁴ published in book form in 1916. As the result of an exhaustive series of experiments and graphic records obtained with the aid of balloons introduced into the stomach, he concludes that the local element in the sensation of hunger is dependent upon the tonus and peristaltic contractions of the gastric musculature, his work confirming and supplementing the earlier findings of Cannon and Washburne.⁵ His experiments included frequent observations on a healthy man with a gastric fistula, on himself and colleagues, on individuals at various ages and in various conditions of impaired health, and on lower animals. It is open to any one of us by the simple experiment of fasting to appreciate the rhythmical character of the hunger sensation. That this rhythmical sensation is associated with an increase in peristalsis and intragastric tension is shown by the occurrence during the hunger phase of borborygmi and of frequent small eructations due to displacement of some of the air from the fundic air-bubble. Although not subscribing to the view that the stomach is insensitive to thermal stimuli, Carlson otherwise confirms the observations of Hurst that the main element in the production of gastric sensibility is muscular tension. Intragastric and also muscular tension may obviously be influenced by many factors, including the tonic and peristaltic activity and the elasticity of the stomach wall itself, the nature and bulk and rate of introduction of the stomach contents, and the patency or otherwise of the pyloric and cardiac sphincters. Upon various combinations and modifications of these factors and upon disturbances of motor rhythm the majority of all gastric sensations, whether normal or morbid, depend, the sensations in each instance originating in the muscle-fibre and being conducted by the nerves distributed to it. Similar properties pertain to all the hollow viscera, and indeed it would be natural to suppose with all of them that the most essential perception of which they should be capable is the perception of states of emptiness and fullness, and of muscular hypertonus and hypotonus. Appreciation of tonus (or posture) and of tension for them is as important physiologically as is the appreciation of light and colour by the eye, of sound by the ear, of touch by the skin, and of position and tension by the skeletal muscles. In brief, the special sense of the hollow viscera, as Hurst and Carlson have demonstrated, and as Brinton⁶ surmised nearly 70 years ago, is their particular form of muscle-sense. In the case of the rectum or the bladder the state of emptiness is the state of comfort or "unawareness," but evacuation is their obvious function. The main function of the stomach is to replenish, and so the state of comfort is satisfaction. Satisfaction occurs when the stomach walls are adequately relaxed so as to enclose or grasp a meal of appropriate bulk and consistency. It does not necessarily follow that emptying of the stomach is immediately succeeded by an increase of tonus sufficient to induce hunger, but too prolonged emptiness results in tonic and peristaltic contractions of a degree sufficient to awaken consciousness in the form of the hunger discomfort, and this at times may even become a painful sensation.

Repletion.

Repletion may give rise to sensations which are mildly uncomfortable or definitely painful, and is experienced when the stomach is overfilled or too rapidly filled with a normal quantity of food or fluid. Gross and rapid over-eating may conceivably, but very exceptionally, cause distension and stretching of muscle fibres; in fact, dilatation of the healthy stomach from over-eating is probably as rare as dilatation of a healthy heart from over-exertion. Generally the sensations of repletion depend upon an increase in tension due to the fact that muscular relaxation has not proceeded *pari passu* with the introduction of food or fluid.

Appetite.

Although such a distinguished and careful observer as Beaumont⁷ stated that "Appetite and hunger belong to the same class of sensations; they differ only in degree," modern observers regard the sensations as having a separate nature and origin. To such an extent do physicians rely on appetite as an index of physical health and loss of appetite as a symptom of physical disease, that it is a matter for some surprise that closer attention is not paid by Carlson to the question of its genesis, and that he seems to stress the psychic elements in its production at the expense of the gastric elements.

The following are the essential differences between the sensations of appetite and hunger. The first is a pleasant sensation; the second unpleasant. The first may occur in an adequately fed subject, may be present even when the stomach contains food in plenty, is stimulated rather than diminished by pleasant foods and beverages, and is only abolished by repletion. The second results only from undue abstinence from food or excessively rapid utilisation of food, is absent when the stomach is filled, and is relieved by eating. The first is a daily experience in health; the second is only an occasional experience under the usual conditions of civilised life. The first has a sustained quality; the second is felt as a recurring or intermittent sensation.

Other senses besides taste may stimulate appetite, and in man sights, smells, sounds, and the general sensory comforts of pleasant environment may all react in its favour. To a great extent it is undoubtedly a "conditioned reflex." The localisation of the appetite sensation is not so accurate as that of the hunger sensation, but this is partly because it is a less clamant spokesman. Some refer it to the pharynx or oesophagus, some to the epigastrium, or to all three. Personally I experience the sensation mainly in the gastric zone. In any case the ability to localise it at all indicates the possibility that, as with hunger, there may be a local visceral process concerned, and there are various clinical, radiographic, and pathological observations which lend support to the view that appetite, while differing from hunger in many respects, has also a local origin in the upper alimentary tract. These observations point to the tonic activity of the gastric and perhaps the oesophageal plain muscle as the probable factor, while, for the appreciation of hunger, peristaltic activity is—as Carlson's experiments suggest—a necessary addition. Appetite may occur without hunger, but hunger seldom, if ever, occurs without appetite. Peristaltic activity (in the same manner as the activity of skeletal muscles) requires for its initiation a certain degree of tension or postural tonus. It may be urged, too, that just as general well-being and preparedness for physical effort are associated in idea and fact with a favourable state of tonus and adaptability of the skeletal muscles, so too digestive well-being and preparedness for digestive effort are associated with a favourable state of what may be termed "anticipatory" tonus in the plain muscle of the stomach or upper alimentary tract generally. Certainly there is a close inter-relationship between the two states, for general well-being and good appetite are associated phenomena, and it will be agreed that appetite is stronger in the vigorous athletic type of individual and that it varies directly with constitution and habit. Gastric tonus from the radiographic point of view shows a similar variation with physical type.

In support of the view that appetite is related to gastric tonus we also have radiographic evidence in certain diseases accompanied by poor or by excessive appetite. Thus hypotonus is a very common finding in sufferers from pulmonary tuberculosis and other debilitating conditions in which appetite is diminished. Conversely in conditions such as duodenal ulcer, in which appetite is increased, hypertonus is frequently recorded. Hypertonus is also described in diabetes. Barclay,⁸ on the basis of radiographic observations, relates the appetite sensation to gastric tonus, and has visualised tonic adaptation in response to such

appetite stimuli as the exhibition of savoury foods or even the mention of a glass of beer to hospital patients.

Of all the diseases in which loss of appetite is liable to develop, in none is it more constant or pronounced than carcinoma ventriculi. Brinton⁶ states that it is present in 85 per cent. of cases. The greater the infiltration of the stomach wall the more profound is the anorexia. Needless to say, anorexia is encountered in malignant disease elsewhere, but generally in the later cachectic phases. In carcinoma of the stomach it is often an early symptom. In "leather-bottle" stomach it may be the only symptom, and may occur independently of any extreme loss of weight, anæmia, or other factors, such as pain and sickness, which would be calculated to induce a secondary anorexia. The following case appears to me to support the contention that appetite may be a particular function of the stomach:—

A man in the middle forties had complained for two years of complete loss of appetite. He was leading throughout this period an energetic life, both physically and mentally. He played games with vigour, but no measures which he could adopt and no treatment prescribed produced the slightest amelioration of his symptom. He had no pain, and his loss of weight was not more than could be accounted for by his diminished intake of food. On clinical and radiographic evidence and the discovery of a complete achlorhydria a diagnosis of "leather-bottle" stomach was made, and at operation the typical appearances of this condition were revealed.

In such a condition the function of tonic adaptability is obviously entirely destroyed; in this special instance the only concomitant symptom was complete destruction of appetite. The anorexia which accompanies acute fevers, fatigue, and neurasthenia is due partly to a relaxation of tonus, which may be present also in the skeletal muscles, and partly to the nervous depression. In a case of advanced "anorexia nervosa" I have seen an unusual degree of atony, or, more correctly, of hypotonus, demonstrated radiographically. In such cases physical exhaustion combines with the perverted and depressed emotions in bringing about the loss of tonus. A similar asthenia probably operates in the case of hunger-strikers and professional fasters, who notoriously lose their appetite in the later stages of their fast. It should, however, be mentioned that Carlson⁴ demonstrated both in man and dogs a tendency to increasing tonus and peristaltic vigour during starvation, and that this persisted when the hunger and appetite sensations had become enfeebled. He attributes this to depression of the central nervous system; it has, however, occurred to me that diminishing adaptability in the muscle coincident with the steadily amplifying tonus (just as with extreme hypotonus or with rigidity of the stomach wall) may be a partial explanation, for a healthy or normal tonus is that from which a normal movement or adaptation can most readily be initiated. Pavlov⁹ showed with animals that appetite stimuli were capable of producing a secretory response, and since secretory and motor responses are both of vagal origin and commonly show a parallel behaviour, it is highly probable that there exists a simultaneous muscular response. Even admitting that there is a strong psychic and memory element in the production of appetite, it seems justifiable to submit that there is also a stimulus transmitted to the gastric musculature which enhances its tone to a sufficient degree to waken consciousness. The necessary degree of tonic activity may be extremely slight and not easily susceptible of demonstration, but when it is considered how small and insignificant are the degrees of tonus in a skeletal muscle which serve to inform us of its posture or the stresses opposed to it the hypothesis becomes at least a reasonable one.

Beaumont⁷ suggested that hunger and appetite might be due to distension of the gastric glands or blood-vessels. Possibly the sudden sensation of warmth or "glow" in the epigastrium, which is sometimes felt at the beginning of a pleasant meal

and which is more constantly induced by alcohol, may be associated with this phenomenon, but the sensation to my mind is quite different from the appetite sensation.

Briefly, to summarise the view of the gastric appetite sensation which I have endeavoured to sketch we may say that *the sensation is in part a memory process and in part a local manifestation of efficient gastric tonus reflexly induced by the memory stimulus, or by the more direct stimulus of seeing, smelling, tasting, or swallowing food, or by some combination of these factors.*

I have digressed into a discussion of appetite because the gastric elements in its production seem to me to have been undervalued, and because in the clinical study of general and gastric disorders we have long been accustomed to rely upon its presence, perversion, or absence as being of such peculiar diagnostic and prognostic significance.

In the foregoing sections frequent use has been made of the word tonus, and it is desirable that the term should be used in its most accepted sense. Sherrington¹⁰ quotes Hughes Bennett's¹¹ definition of "reflex muscular tonicity" as being "that slight constant tension which is characteristic of healthy muscle." In Sherrington's words "reflex tonus is in short reflex posture." The recent investigations of Hunter¹² and Royle¹³ have shown that the maintenance of posture both in skeletal and visceral muscle is a function of the sympathetic.

When the stomach is filled so as to raise the intragastric tension, the tension, as demonstrated by Moritz,¹⁴ quickly falls again to its previous level by an adaptation of the musculature so as to accommodate comfortably the increased content. The state of tension of the stomach muscle is its postural tonus, and, as Sherrington points out, we might speak of its "quarter-pint" and "half-pint" postures. Tonus and tension are not synonymous, for, without altering its posture, the tension in a muscle-fibre may be raised by the application of an external pressure or a stretching force. By the automatic regulation of intragastric and muscular tension we are in health spared from experiencing all symptoms—apart from those which we rather dimly appreciate in the guise of hunger, appetite, and satisfaction, and which depend upon an exaggeration or reduction of muscular tension of one kind and another inadequate for the production of real pain or discomfort. If, however, the stomach be too rapidly filled, or be allowed to remain too long empty, or if through exaggerated vagal stimulation in physical disease or emotional stress, or from other causes, a condition of exaggerated tension results, then discomfort or pain is developed.

The conception that the secretory behaviour of the stomach or the chemical reactions of its contents may directly influence sensibility is discounted in many ways. Hurst³ showed that with the single exception of alcohol none of the chemical stimulants which he employed, including hydrochloric acid in the highest physiological concentration, are capable of promoting gastric sensibility. In the series of 100 healthy men investigated by Bennett and Ryle¹⁵ every variety of secretory response was encountered. In four cases there was complete achlorhydria throughout the test. In another group the readings were so high as to have suggested, on earlier conceptions, some pathological condition. All of these men were free from dyspeptic symptoms, and the only one of them who mentioned an unusual readiness for meals was one of a small group showing a normal range of acidity but an unusually rapid rate of emptying.

In the light of existing knowledge it thus becomes fair to conclude that we have in the "symptoms of health"—hunger, appetite, satisfaction, and repletion, and the readiness with which they appear and disappear—a measure not only of the muscular sensibility, but also of the muscular and motor efficiency of the stomach; but these symptoms give no index of its secretory behaviour.

THE MOTOR FUNCTIONS OF THE STOMACH.

Radiographic examination of the stomach after an opaque meal has probably contributed more to the accurate diagnosis of organic gastric disease than any other method of physical inquiry excepting surgical exploration. Its contributions to the study of gastric function have been less valuable and some of its earlier conclusions were misleading. This was due mainly to an inadequate study of the normal. Until recently most of the literature of gastric radiology has been provided by observers concerned with the examination of patients and often unconsciously actuated by the desire to make a diagnosis, or at least to find an explanation for symptoms for which the clinician had not provided a suitable explanation.

It is now recognised that the normal stomach may present a wide variety of appearances after the administration of a bismuth or barium meal; that the same stomach may behave differently on different occasions; and that a number of conditions formerly reported as abnormal are really consistent with perfect health. Hurst and Morton,¹⁶ as long ago as 1907, drew attention to the great variations found in healthy students during radiographic examinations of the alimentary tract. If at an earlier date a large series of healthy men and women had been carefully examined and reported upon we should have been spared many difficulties and doubts in clinical work. The functions of the stomach which may be observed radiographically are its tonus, peristaltic activity, and emptying-rate.

The *tonus* of the stomach may to some extent be judged from the position, size, and shape of its shadow. Of these the position alone is easily measurable; in the normal attitudes of health it is only influenced in a very small degree by the state of the abdominal musculature and other external factors. An important investigation has been published by Moody, Van Nuys, and Chamberlain,¹⁷ who examined 600 healthy men and women, described remarkable variations, and concluded that the use of such terms as gastropexia is unjustifiable, and that the position of the stomach may be so low or so high in healthy persons that these variations cannot in themselves be regarded as evidence of disease. Table I. briefly epitomises their findings.

TABLE I.—(Moody, Van Nuys, and Chamberlain.)
Position of the Stomach in 600 Men and Women Students.

Position of the greater curvature with reference to the iliac crests.	Percentage of subjects (nearest whole figure).	
	Men.	Women.
More than 2 inches above	2	1
" " 1 inch " " " " " " " "	5	2

Less than 1 inch below	23	19
More " " 1 " " " " " " " "	27	21
" " 2 " " " " " " " "	16	22
" " 3 " " " " " " " "	6	17
" " 4 " " " " " " " "	3	8

It will be noted that hypertonus, as would be expected, on ordinary clinical experience, is more commonly an attribute of the male sex and hypotonus of the female sex. Employing Schlesinger's¹⁸ classification into orthotonus, hypertonus, and hypotonus, Moody, Van Nuys, and Chamberlain found in their male series that orthotonus was present in 79 per cent. of cases; hypertonus in 17 per cent.; and hypotonus in 4 per cent. It is interesting to compare these figures with those obtained in the normal series of Bennett and Ryle,¹⁵ who found normal secretory curves in 80 per cent. of cases; hyperchlorhydria and high normal curves in 15 per cent.; and hypochlorhydria and achlorhydria in 5 per cent. In their female series Moody, Van Nuys, and Chamberlain found orthotonus in 78 per cent.; hypertonus in 7 per cent.; and hypotonus in 15 per cent.

Campbell and Conybeare¹⁹ examining independently the same group of healthy students by means of the fractional test-meal and radiographically, were able to demonstrate a definite relationship between hypertonus and hyperacidity on the one hand and hypotonus and hypoacidity on the other. They also correlated these phenomena with gastric motility and the general physique of the individual. Hypertonus, hyperacidity, and rapid emptying (of barium) occurred most frequently in men of the broad-chested, vigorous, athletic type; hypotonus, low acidity, and slow emptying (of barium) for the most part in narrow-chested men below the average of physical development, and not taking regular exercise. Between these extreme types was a much larger group showing normal tonus and normal acidity. Tables II. and III. illustrate certain of their findings.

TABLE II.—(Campbell and Conybeare.)
Showing the X Ray Findings in 50 Men with Hyper- or Hypochlorhydria Compared with the Normal.

	Percentage found in which the stomach was—		
	High or rapidly emptying.	Normal.	Low or slowly emptying.
Of six men with hyperchlorhydria (Group 6) ..	67	33	0
Of 39 men in whom the stomach was normal (Groups 3, 4, 5) ..	15	70	15
Of five men with hypochlorhydria (Groups 1 and 2) ..	40	0	60

TABLE III.—(Campbell and Conybeare.)
Showing that in Most Cases a Subject who was Picked Out as Unusual by X Rays was also Unusual by His Test-meal.

	Percentage found as normal by test-meal.	Percentage found unusual—i.e., Groups 1, 2, or 6.
Of 31 subjects normal by X rays	93	7
Of 15 subjects unusual in one particular by X rays ..	60	40
Of eight subjects unusual in both particulars by X rays ..	38	62

The association of particular gastric appearances with particular physical attributes has long been recognised by radiologists. In a less distinct way the association of physical type and certain dyspepsias has long been observed by physicians, who would, perhaps, go further and associate certain temperaments and nervous attributes with certain physical and dyspeptic types. Thus it would, I believe, be agreed that the patient with duodenal ulcer is frequently either of the vigorous, broad-chested type, or lean and nervous and fittingly described as a "hypertonic" individual, and that he commonly shows brisk and even exaggerated tendon reflexes. At the opposite end of the scale the female patient with visceroptosis may be described as "hypotonic" and commonly shows sluggish tendon reflexes. With normal subjects there have not, so far as I have been able to ascertain, been any previous anthropometric studies of such a complete kind as those of Campbell and Conybeare, and Moody, Van Nuys, and Chamberlain. Carman,²⁰ from the point of view of the clinical radiologist, writes as follows: "Thus I feel that the chief test by which the stomach is to be adjudged of normal tone is its correspondence to the habitus of the individual, and not its form, size, and position alone. With the broad habitus the tone may vary from orthotonus to hypertonus. With the normal habitus it may be expected to vary from orthotonus to at least slight degrees of hypotonus. With the enteroptotic habitus, hypotonus is the rule. . . ." The observations quoted above lend strong support to this useful generalisation.

If the recognition of variations in different individuals is important the recognition of variations in the same individual at different times and under varying conditions is equally so. Barclay,⁸ in a valuable dissertation on the normal stomach, emphasises the need for greater familiarity with these variations, and states that: "The alterations possible in the shape and size of the normal stomach are many, and apart from displacements such as by collections of air in the intestines, they are almost all due to variations in tonic action." He mentions an experiment on three healthy students conducted by Morison, who reported that the appearances on one occasion were of the normal "J" and "cow-horn" types; on a subsequent occasion "not one of them was of the so-called normal type, various stages of atony being present." Barclay refers also to the remarkable alterations in the shape and position of the stomach as the result of disgusting smells, sudden emotion, and fright, and in association with feelings of faintness. On one occasion he saw the lower border of a normal orthotonic stomach drop nearly 3 inches when the patient was startled by a banging door. He attaches great importance to the tonic action of the oblique fibres of the stomach and suggests for them a sling-like supporting mechanism, quoting the anatomical investigations of Jefferson,²¹ and indicating that they probably have a separate purpose and can contract independently of the circular and longitudinal fibres. Even the remarkable "cup and spill" stomach, in which the food collects in the upper portion of the organ and spills over into the lower portion, is referred to by Barclay as "another picture of the normal stomach." He regards this appearance as being due to the action of the oblique fibres "contracting or remaining in posture."

The peristaltic activity of the healthy stomach is chiefly a function of the mid-gastric and præ-pyloric portions. It begins shortly after the ingestion of the meal, but its advent may be retarded or even inhibited by nervous states and emotions. The depth of the waves shows wide variations; it is usually greater in association with hypertonus and less with hypotonus. Position may also influence peristaltic activity, which is commonly increased when the subject is lying prone.

Motility or emptying-rate may be usefully studied by radiographic methods, although it is doubtful whether the information thus obtained is as accurate as that furnished by the fractional test-meal. Again, the widest variations are encountered. According to Carman,²⁰ "It would seem that by no simple test can sharp and constant lines of demarcation be drawn between hypermotility, normal motility, and hypomotility." The conditions of the test must obviously be standardised, for differences in the opaque salt employed, in the bulk and character of the meal, and the management of the patient after its ingestion may all have an influence on the rate of emptying. To Haudek²² we are indebted for the double-meal method of examination and the establishment of the six-hour limit. With the barium meal usually employed in this country and given to a fasting subject the stomach should be completely empty within six hours. The average emptying-rate in patients without obstructive lesions is considerably less than this and may be said to lie between three and five hours. I have not succeeded in finding a reference to any accurate radiographic study of the emptying-rate and its variations in a long series of healthy men or women, but P. J. Briggs (communicated) in 100 patients without gastric or duodenal disease obtained the following figures. The stomach emptied in two and a half hours in 1 per cent.; in three hours in 6 per cent.; in three and a half hours in 9 per cent.; in four hours in 44 per cent.; in four and a half hours in 32 per cent.; and in five hours in 8 per cent.

The relationship between gastric tonus and emptying-rate is not so definite as might be supposed. A hypertonic stomach does not necessarily empty quickly nor a hypotonic stomach slowly, and much

depends on the nature of the meal employed. In health as well as in disease the behaviour of the pylorus is apparently the most important factor regulating the rate of emptying.

Although the fractional test-meal can obviously give no direct information relative to tonic or peristaltic activity, it is a valuable test of motility. Levy²³ advocates the gastric tube as being more accurate than X rays for gauging the emptying-rate of the stomach, and in my own clinical work I have formed the same opinion. As will be shown later, the rate of emptying is the most constant and accurate of all the findings with the fractional method. The average rate of emptying with the standard gruel meal in a healthy man is two hours and the extreme variations are one hour and two and three-quarter hours. Briggs, examining radiographically a group of 20 men from the normal series of students studied by Bennett and Ryle and employing a meal of approximate density to the standard gruel meal, found closely comparable emptying times, the average rate of emptying, irrespective of tone, being two hours and eleven minutes.

The table quoted hereunder (Table IV.) illustrates the rate of emptying as judged by the fractional

TABLE IV.—(Baird, Campbell, and Hern.)
Rate of Emptying of the Gruel Meal. Figures given as Percentages.

	Average time of emptying.	1 hr. or before.	Stomach contains no starch at (hours)—						
			1½	1¾	1½	2	2½	2¾	or later.
This series (57 men) ..	2.1	5	7	14	9	17	16	10	22
Bennett and Ryle (100 men) ..	1.9	0.6	3	7	13	17	14	18	22
Combined (157 men) ..	2.0	5.5	4	9.5	12	17	15	15	22

test-meal in the two series studied by Bennett and Ryle¹⁵ and by Baird, Campbell, and Hern.²⁴ The extreme variations from the average normal figure are seen to be not more than 50 per cent. of that figure—a much smaller percentage variation than obtains with other measurable quantities, such as gastric acidity. The one hour test of Ewald can obviously give no such accurate estimate of motility.

THE SECRETORY FUNCTIONS OF THE STOMACH.

The fractional method of gastric analysis was described by Rehfuß²⁵ in America in 1914, but did not attract attention in this country until 1919. Since then its numerous advantages over the older one-hour test of Ewald have resulted in its adoption both as a method of physiological inquiry and as an aid to clinical work in many hospitals and schools in this country. Douglas and Priestley²⁶ have recently incorporated this method in their practical text-book on Human Physiology. It has formed the basis of many gastro-enterological studies in recent years, and with its help many of the classical observations of Pavlov in the case of dogs have now been confirmed in man. Indeed, a voluminous literature of the fractional test-meal has grown up on both sides of the Atlantic, but it has for some reason found less favour on the Continent. It is unnecessary to refer here to the technique, for full descriptions of the method have been given elsewhere.^{27 28 29}

The advantages of the fractional method may be summarised as follows:—

1. It permits of accurate measurement of the fasting juice and a study of its mucus, bile, and cell content, together with estimations of its free and total acidity.

2. It provides in graphic form an indication of the chemical processes at each stage of gastric digestion and detects late rises in acidity and such phenomena as continued secretion. By recording the times at which bile-regurgitation occurs it gives an indication of the occurrence of pyloric relaxation and duodenal reflux.

3. It determines with considerable accuracy the emptying rate of the stomach for a standard meal.

4. By combining chloride estimations with those for free and total acidity it furnishes information relating to the factors causing neutralisation and so indirectly again to the functions of the pylorus.

5. In pathological cases the presence of food residue in the fasting specimen, of blood or pus in this or subsequent specimens, the odour of the samples and other physical characters may also be observed.

Amongst the possible fallacies which have to be considered are the following:—

1. The action of the tube as a foreign body in the stomach.
2. The stimulation of excessive salivation which would tend to dilute and to a less extent to neutralise the free acid.

3. Diminution of the psychic secretion by the circumstances of the test and the unappetising character of the meal.

4. Emotional inhibition or exaggeration of secretion during the test.

5. Duodenal regurgitation from retching.

6. Variations from day to day in the curve of a given subject.

7. Variations in acidity at different levels in the stomach.

8. Variations with sex and age.

These will be discussed seriatim.

1. Inert foreign bodies in the stomach do not apparently influence its secretory behaviour. This was demonstrated by Beaumont⁷ in the case of man and by Pavlov⁸ in the case of animals.

2. A foreign body in the oesophagus may, however, induce a vigorous reflex salivation, and acting in this way, the gastric tube can cause an artificial hypo-acidity, as was shown by Bennett and Ryle.¹⁵ In their series all cases of excessive salivation were excluded. In clinical work it is occasionally necessary to insist on expectoration of saliva or to make allowance for its occurrence in interpreting the curves. The proportion of cases in which it occurs has been small in my experience.

3. In man there is a certain amount of continuous secretion which can at all times be shown to be present excepting in cases of genuine achylia, but the importance of the psychic secretion is uncertain. Carlson⁴ concludes that "the significant appetite secretion in man is that induced by tasting and chewing good food," and considers that Pavlov placed too great an emphasis on the secretion as induced in a hungry animal by seeing and smelling food. Haneborg²⁹ also doubts the importance of psychic secretion in man. Bennett and Venables³⁰ failed to demonstrate it in students, and in a few unpublished observations on myself I could not convince myself of its occurrence. I think, however, that the question is deserving of fuller inquiry. It cannot be denied that the insipid nature of the gruel, and the absence of any need for mastication, would tend to minimise appetite secretion (if it occurs), but this should be considered rather an advantage than otherwise, since it must render the conditions more comparable for different individuals.

4. That emotional inhibition of secretion may occur has been shown by various authors, including Hornburg,³¹ in the case of the continued or appetite secretion in a child, and more recently by Bennett and Venables,³⁰ who greatly modified the acid curve with the standard meal and lengthened the emptying time of healthy individuals by suggesting nausea or anxiety to them while under the influence of hypnosis. Generally the emotional stresses of the test are not significant. The proportion of cases in which there is real difficulty in swallowing the tube or serious retching or nausea is small. Both with hospital and private patients the initiation and supervision of the test can safely be left to nurses who have had a little preliminary instruction and can appreciate the importance of making light of the difficulties. Among many hundreds of cases in the investigation of which I have been directly or

indirectly concerned, I can call to mind less than half a dozen in which emotional factors prevented the swallowing and retention of the tube, and gross variations in the curves which could reasonably be attributed to mental or physical distress have been rare.

5. Just as salivation may alter the conformation of the curves of acidity by dilution and neutralisation, so, too, an abnormal amount of duodenal regurgitation consequent upon retching and recognisable by the presence of unusual quantities of bile may create a fallacy. Continued retching is even more rare in my experience than continued salivation. Nevertheless, admitting that there is often a disturbing psychic factor on the occasion of the first test, it is obvious that more reliable findings would be obtained by repetitions of the experiment. In clinical practice this is seldom feasible.

6. It is important to dispose of the criticism that there may be wide variations in the responses of the same individual from day to day. On the analogy of the variable tonic and peristaltic behaviour of the stomach secretory variations would also be anticipated, and such changing factors as appetite and hunger and minor differences in the conditions of the test might be expected to find reflection in the acid curves. We do not expect constant and identical behaviour on the part of other glands, such as the salivary and sweat glands, even under closely parallel conditions. With the fractional test-meal the conditions are, so far as possible, standardised by carrying out the test at the same time in the morning after the night's rest, by employing the same meal and the same method, and by encouraging the subject to occupy his or her mind with a book or other diversion during the period of the experiment. With these precautions the variation in the results obtained from the same individual on different dates have generally been slight. Where they appear more considerable the general conformation of the curve is maintained and the rate of emptying is remarkably constant. Subjects with low curves or achlorhydria show low curves or achlorhydria; subjects with high curves show high curves on subsequent occasions. The four curves here given were obtained in my own case on the dates indicated. (Chart 1.)

Bell and MacAdam³² performed the interesting experiment of examining the same man on no less than 20 consecutive days. They found the rate of emptying remarkably constant. On 13 occasions it was one and a half hours. On five occasions it was one and three-quarter hours; on two occasions it was two hours. The general conformation of the curves was similar, but the curve obtained on the first day was distinctly lower than on any subsequent day.

7. Gorham³³ and Kopeloff³⁴ have criticised the fractional test-meal on the ground that acidities at different levels are sufficiently divergent to render the ordinary conclusions unreliable. It need hardly be pointed out that it is a part of the technique to keep the tube at the same level during the whole period of the test, and having regard for the fluidity of the gruel meal and the constant activity of the stomach during gastric digestion, it is difficult to believe that the contents can escape thorough mixing. On studying the reports of Gorham and Kopeloff, it appears that they did not employ the gruel meal. Kopeloff employed the tea and toast meal, and Gorham shredded wheat and water. With meals of this nature it is obvious that a certain amount of sedimentation will be liable to occur; that the farinaceous portions will be mixed with saliva; and that there will be greater variability in the fluidity of the samples. The experiments of Gorham and Kopeloff thus require repetition with the gruel meal. Even allowing that their criticism may be reasonable from the scientific standpoint, it need not necessarily be held to invalidate the practical utility of the test; Wheelon³⁵ supports Gorham's findings, but does not condemn the clinical employment of the test-meal. Fractional analysis is chiefly employed as a clinical test, and can never, by any stretch of imagination, be regarded

as an accurate chemical procedure. It must be clearly appreciated that its findings merely portray in a general way the results of the numerous processes influencing the chemistry of the gastric contents from moment to moment. A similar lack of appreciation of the objects and limitations of the test attach also to the contentions of Cole and Adie³⁵ and of Kopeloff,³⁴ who have urged the inadequacy of the usual titration methods and the importance of hydrogen ions and buffer salts in the estimation of gastric acidity. The time and attention expended

of the instances of hyperchlorhydria after 40 were in men aged 60 and upwards.

In summary we may conclude that the practical utility of the fractional method as a means of studying gastric function has been sufficiently established; its value in clinical work is great, but it must not be regarded as a "diagnostic" test excepting in the presence of obstructive lesions.

The findings in regard to gastric secretion and motility and the factors bringing about neutralisation in the normal series of 100 healthy students examined by Bennett and Ryle may be summarised as follows:—

The Fasting Juice.

This varied from 10 to 150 c.cm. with an average of 54 c.cm. Bile was present in 40 per cent. of fasting specimens. The range of free acidity was from 0 to 60 (per cent. of decinormal soda), taking all the cases, and from 0 to 22 in the 80 cases providing the figures for the standard chart. (Chart 3.) In a series of individual examinations of my own gastric juice carried out over a period of 31 days the quantities varied from "a few c.cms." obtained with difficulty to "20 or 30 c.cm." obtained with ease. It should be stated that my curve of free acidity corresponds closely with the mean of the 80 per cent. of normal students. The free acidity of the specimens varied from 0 to 22 and the total acidity from 4 to 38 with a difference between free and total acidity ranging between 10 and 15. During a portion of this experiment I was on a diet as nearly as possible salt-free. Over this period the fasting specimen was scanty and obtained with difficulty, but the response to the standard test-meal was not influenced. Bile in the fasting juice was present or absent with equal frequency and sometimes absent in the first syringe-ful and present in the second, suggesting that either aspiration or automatic reflux from the duodenum had occurred.

Acidity.

The percentage of free acid in 91 of the cases showed a steady increase after ingestion of the meal, reaching a maximum at one and a quarter hours, and was thereafter followed by a gradual fall. The extreme variations in the curve of the acidity are shown in Chart 2. Chart 3 shows the variations in the 80 per cent. selected to compose the standard for comparison in clinical work. There is generally a difference between the curves of free and total acidity of 10 to 15 per cent. N/10 NaOH, and they run closely parallel. Four cases in the series—i.e., 4 per cent.—showed complete absence of free acid throughout the test on each of the several occasions on which they were examined. Confirmation of this finding was obtained by the alveolar CO₂ method of Dodds. Campbell⁴³ criticises this observation and suggests that the incidence of genuine achylia in health may be less than 4 per cent. and that if the total chlorides had been estimated in these cases it would possibly have been found that some of them were not cases of achylia, but of achlorhydria due to excessive neutralisation. In the series examined by himself in collaboration with Baird and Hern there were three cases of achlorhydria, but only one of these was shown to have a constant achlorhydria and subsequent physicial studies raised doubts as to the fairness of classifying him as a healthy subject. Eight cases (Bennett and Ryle's series) showed hyperchlorhydria (acidity above 60 or 0.219 per cent. HCl) and of these five gave climbing types of curve akin to those encountered in pathological conditions such as duodenal ulcer. Six cases in the series showed a normal range of acidity, but unduly rapid emptying. The important conclusion to be drawn from these observations is that neither hyperchlorhydria nor achlorhydria can in themselves be regarded as pathological findings.

Bile Regurgitation and Secretion of Mucus.

Bennett and Ryle, and Baird, Campbell, and Hern refer in their two series to the frequent presence of bile in the fasting juice and also in the later specimens of the test-meal. Its appearance in the later specimens

CHART 1.

Showing response of same individual on four different occasions. Standard gruel meal. (a) 18/1/20; (b) 25/1/20; (c) 1/2/20; (d) 9/5/20.

on such accurate methods would be out of all proportion to the results obtainable. Haneborg³⁹ states that the curve of hydrogen-ion concentration in fractional specimens follows the curve of free acidity fairly closely. Norgaard,³⁷ comparing pH estimations with titration results, concludes that "the titration method can therefore still be recommended as the most convenient and diagnostically adequate method of acid determination in test-meal investigations."

8. In regard to sex variations, Fowler and Zentmire,³⁸ examining the resting juice in healthy women, obtained results in all ways similar to those obtained in men by Fowler, Rehfuess, and Hawk.³⁹ I have not been able to find a reference to an extended series of test-meals in normal women. Kopeloff³⁴ examined ten young pupil nurses, each on several occasions. A study of the curves shows them to be mostly of normal type and conformation, but the acidities run at a slightly higher level in comparison with the chart obtained from the normal male series of Bennett and Ryle; this may be accounted for by the difference in the nature of the meal. Wright⁴⁰ investigated 250 school-children between the ages of 6 and 15 with the Ewald test and found the free and total acidity to give the same figures as in adults. He observed no essential difference between the sexes. Four cases of achlorhydria were encountered, but the finding was not constant in all four. Bell,⁴¹ on an analysis of 425 test-meals in hospital and private patients, concluded that women preponderate over men in the low curves in the proportion of 68.4 to 42, and men over women in the high curves in the proportion of 100 to 61.2. It is improbable that pathological states would greatly influence the sex incidence of the different types of secretory response. A comparable, though wider, disproportion in regard to tonus in the two sexes in health has already been mentioned. It has been stated that there is a tendency to diminished secretion with advancing years. Haneborg⁴² recently subscribed to this view, but Bell found no confirmation for this in the series just referred to. Actually he found hyperchlorhydria to be more common after than before 40, and a third

often coincides with the commencement of the fall in acidity and probably accompanies the duodenal reflux which is considered to be an important factor preventing hyperacidity in the stomach. Baird, Campbell, and Hern found bile regurgitation to be rather more frequent in the cases with hyperchlorhydria. The amount of mucus present can only be judged visually. It becomes more plentiful towards the end of the meal, is sometimes mingled with a clear juice of low acidity, and probably represents the mucous portion of the protective alkaline secretion of the pyloric mucous membrane. There is generally an inverse relationship between mucus content and acidity.

Rate of Emptying.

This has already been discussed under the heading of gastric motility. In Bennett and Ryle's series the average rate was 1.9 hours; in the combined series of Bennett and Ryle and Baird, Campbell,

be accompanied by rapid emptying; hyperchlorhydria to occur in men leading a more active life and more commonly to be associated with delayed emptying. The emptying-rate of the heavier barium meal showed an entirely different relationship, and, presumably by reason of its weight, was slower in association with hypotonus. Indeed, the weight of the barium constitutes a very real fallacy in radiographic estimations of motility.

A review of the results of Campbell and Conybeare, and Baird, Campbell, and Hern, in the light of clinical experience, seems to justify their conclusion "that certain anatomical and physiological variations present in health may be the physical basis of the subject's diathesis or tendency to develop certain gastric disorders under appropriate influences." Their findings thus lend support to the contentions of Hurst⁴⁴ in regard to gastric diatheses, provided we agree to accept "diathesis" as implying a tendency to "retain" or to "develop" and not a tendency to "acquire" a disease. We have, as Hurst has suggested and I shall endeavour to show, evidence that the physiological characters or habitus of the stomach may determine its dyspeptic reactions to various stimuli, and there is little doubt that the physiological characters may also help to determine the perpetuation of such a lesion as duodenal ulcer. There is, however, no evidence that the physiological characters render the stomach or duodenum more liable to acquire a lesion in the first instance.

Mention must be made of the indirect method described by Dodds,⁴⁵ who showed that there is a definite respiratory response to meals. Of this response the chief characters are an initial rise in the alveolar carbon-dioxide pressure of from 2 to 6 millimetres; later, after three-quarters of an hour, a fall of about the same amount below the original level; and finally a return to the original level. Bennett and Dodds,⁴⁶ comparing the results obtained by this method and by the fractional test-meal, found that they confirmed one another both in normal and abnormal groups of cases.

Response to Different Foods.

The response to different foodstuffs may, as I have shown elsewhere,⁴⁷ be readily studied by the fractional method. The accompanying charts (4, 5, 6, 7, 8, and 9) illustrate the response in my own case to

and Hern it was two hours. It appears to be very constant for the individual and shows a limited range of variability in the male community. Whereas the free acidity in healthy persons can vary from the mean by 300 per cent. and more, and tonus, if it were measurable, would probably be found to vary in at least an equal degree, the emptying rate varies by not more than 50 per cent. from the mean.

The findings of Campbell, Baird, and Hern^{24 43} have frequently been quoted above. These observers repeated the experiments of Bennett and Ryle with a further series of healthy students, examining 57 men in all. They concluded as follows: "The general results of Bennett and Ryle on the rate of emptying the stomach and the range of acidity of the gastric juice after a gruel meal are confirmed in a further series of students," and "that the fractional test-meal does give a true idea of the course of digestion in the stomach, provided certain limitations about its accuracy are recognised." They also made interesting observations on the association of physical fitness with gastric type. In the normal and high normal groups they found that there is no association between the degree of acidity, the rate of emptying, and the physical fitness of the subject. Outside this range, however, hypochlorhydria or achlorhydria is more likely to occur in men leading a sedentary life and to

meals of milk, skim-milk, an emulsion of cream, tea and milk, water, and a solution of sugar in water. The response to water, according to Ivy,⁴⁸ and also to Moffatt, Mitchell, and Powell,⁴⁹ is too variable for it to be employed as a test, and the long sojourn in the stomach of protein and fatty meals renders their use impracticable in routine work. The "exciting" influence of protein and the "inhibitory" effect of fats is demonstrated in the milk or skim milk and cream feeds respectively; the excitation and inhibition are as much in respect of motility as of secretion. The slowly climbing curve in the milk test-meal is closely similar to curves obtained with the gruel meal in pyloric stenosis; this similarity and the high point of acidity attained depend on delayed emptying rather than upon increased secretion. Skim-milk produces a curve similar to that obtained with gruel, except that there is a wider interval between free and total acidity owing to the combination of acid and protein. The cream, therefore, seems to be the factor responsible for the delay in the whole milk meal. The inhibitory effect of fats is probably due to their physical characters, and by imparting an insoluble pellicle to the mucosa they may be said to act in the same way as the excessive mucous secretion in gastritis which "blocks" the secretory and motor responses normally due

to the contact of soluble food with the mucous membrane.

Haneborg,²⁹ investigating the gastric response to supposed stimulants of appetite, concludes (as also did Carlson⁴) that bitters have no effect upon secretion; that coffee has a definite stimulant effect upon secretion; and that soup and extracts have a definite stimulant effect which is not due to their aromatic qualities, but, as with coffee, to certain xanthin bodies or purin bases. Pure albuminous substances such as egg-white produce no such effect. He claims that there are three classes of secretory response: (1) Psychic secretion (very insignificant in man); (2) secretion physically excited by water and all kinds of food; and (3) a chemical secretion excited by xanthin and caffeine on absorption, by the formation of a gastric secretin.

THE FUNCTIONS OF THE PYLORUS.

No discussion of gastric function would be complete without a reference to the modern views on the functions of the pylorus. An appreciation of its mechanisms in health is essential for a proper understanding of many of the symptoms of disease. Apart from controlling the exit of the stomach contents in such a manner as to prevent food entering the duo-

denum and Crohn⁵² have regarded regurgitation from the duodenum as the main mechanism obviating hyperacidity, and Bennett and Ryle,¹⁵ and Bolton and Goodhart⁵³ have subscribed to the same view.

CHART 4.

Milk test-meal (one pint). The straight line represents total acidity and the dotted line free HCl.

CHART 3.

Standard chart (Bennett and Ryle). The shaded area represents the limits for free HCl of 80 per cent. of normal people.

denum at too great a rate and in too indigestible a form the pylorus has been held to be the most important agent regulating the acidity of the gastric chyme. Boldyreff⁵⁰ was the first to draw attention to this particular function. Rehfuess and his collaborators⁵¹

Hunter⁵⁴ found marked hyperchlorhydria, with curves of the "climbing" or "plateau" type, in seven out of eight cases of gall-stones obstructing the common duct and attributed this to the absence of bile and pancreatic secretion. Other factors normally preventing hyperacidity include the diluting and neutralising effects of the saliva and the alkaline secretions of the pyloric mucosa. Campbell,⁴³ on the basis of a very ingenious experiment in which the factor of duodenal regurgitation was eliminated, considers that greater importance should be attached to the alkaline secretion of the pyloric part of the stomach. All of these factors naturally call for consideration in reviewing the mechanism of physiological and pathological hyperchlorhydria and hypochlorhydria. In an earlier paper⁵⁵ I concluded that the important factors promoting pathological hyperacidity were (1) an excess of secretion; (2) pyloric hypertonus preventing duodenal reflux. These I regarded as the essential factors in the ordinary case of a slowly emptying stomach, but with a rapidly emptying organ I suggested that the rapid emptying itself was an essential factor, since secretion (whether normal or excessive) into a steadily diminishing volume must entail a steady rise in the percentage acidity. Theoretically, it would only require a certain degree of gastric hypertonus to prevent duodenal reflux altogether; actually, of course, the tonus must vary from moment to moment, so that even with a hypertonic organ the intragastric pressure at times (though less frequently and less completely than with normal tonus) falls below the intraduodenal pressure. Apperly⁵⁶ subscribes to the view that increased intragastric tension is a cause of hyperchlorhydria and believes that positive forces in the duodenum normally play a part in the regulation of alkaline reflux. Important observations by Bolton and Goodhart,⁵³ and later by Campbell⁴³ and his collaborators on the estimation of chlorides in fractional specimens have thrown further light on the influence of duodenal regurgitation. These workers rightly point out that without chloride estimations it is impossible properly to interpret hyperchlorhydric and achlorhydric curves. When free acid is present in excess chloride estimations alone can distinguish between a positive hypersecretion and a failure in neutralisation. When free acid is absent chloride estimations alone can distinguish between achylia and achlorhydria due to excessive neutralisation.

Bolton and Goodhart and Campbell conclude that the pylorus is the main factor controlling duodenal reflux. I believe, however, that a clearer conception is required of what we mean when we employ the term pylorus in this sense. It is evident that whatever part the opening and shutting of the sphincter may

cussed later suggest that acidity remains high after gastro-jejunostomy in the cases with hypertonus and rapid emptying, and that the most effective neutralisation occurs in the cases with hypotonus and slow emptying.

The Control of the Pylorus.

Cannon's⁵⁷ views on the acid control of the pylorus so long accepted have recently been called in question. McClure, Reynolds, and Schwartz,⁵⁸ on the basis of radiographic experiments, conclude that "acid is not the principal factor controlling the opening and closure of the pyloric sphincter in man." Egan,⁵⁹ also on X ray and experimental evidence, concludes that the usual view is unsatisfactory, and Baird, Campbell, and Hern,⁴³ with simultaneous gastric and duodenal intubation, showed that "acid in the duodenum does not necessarily close the pylorus, for the most rapid emptying took place at a time when the duodenal contents were unusually acid." The observation that extreme hyperchlorhydria and complete achylia may occur in healthy men with normal digestion and in patients without gastrointestinal symptoms, and that there is no fixed relationship between acidity and emptying-time also suggests that the acid factor in pyloric control is not an essential one. Where a relationship between a secretory anomaly and emptying-rate is demonstrable it is just as reasonable to regard the high or low acidity as the result and not the cause of the pyloric hypertonus or hypotonus. Two clinical observations, however, require further consideration. The first is the relief of pain in duodenal ulcer by the administration of alkalies. Hurst^{3 60} has regarded this as due in part to the lessened acid control of the pylorus; but I shall later suggest a slightly different explanation. The second is the immediate relief by the administration of hydrochloric acid of the gastrogenous diarrhoea accompanying achylia. In this condition the necessary dosage of acid is so small (30 minims three times a day of the dilute Pharmacopoeial solution is usually enough) and the effect is so prompt that it is difficult to suppose that enhanced digestive or bactericidal action can be the relieving factor. This effect may be due to increased pyloric

CHART 5.

Skim-milk test-meal (one pint). The straight line represents total acidity and the dotted line free HCl.

play in assisting or preventing alkaline reflux, there must also be a simultaneous adjustment of intragastric and intraduodenal pressure. The mere relaxation of the sphincter, for instance, would not allow regurgitation if the pressure in the pars pylorica did not at the same time fall below the pressure in the duodenum. The high position of the pars pylorica in relation to the duodenum in the hypertonic or "steer-horn" stomach is an additional factor opposing duodenal reflux, while its low position in the hypotonic or "J"-shaped stomach would facilitate reflux, at any rate in the erect posture. The pylorus consists of the pyloric sphincter and the valve formed with its covering fold of mucous membrane; anatomically the sphincter is a continuation of the præ-pyloric circular muscle layer and probably works in unison with it. On this hypothesis it is reasonable to suggest that a general hypertonus of the whole pars pylorica by causing unusual disparity between intragastric and intraduodenal tension, and not a simple closure of the valve, is the essential factor predisposing to hyperchlorhydria. Conversely, hypotonus of the pars pylorica as well as of the sphincter would predispose to hypochlorhydria. The pyloric antrum is of tubular form in the normal "hypertonic" stomach, and with duodenal ulcer (in which hyperchlorhydria is more constantly present than in any other condition) general hypertonus is commonly demonstrable. Eliminating the services of the sphincter in cases of duodenal ulcer by a gastro-jejunostomy does not necessarily abolish the hyperchlorhydria as it should do if the sphincter alone were to blame. Clinical observations to be dis-

CHART 6.

tonus, but another possible explanation is an increased output of pancreatic secretin and enhanced digestion in the small bowel.

Carlson⁶¹ has recently shown in animals that not only acid but mechanical and even alkaline stimulation of the duodenum can produce pyloric closure, and considers that this is the result of simple sensory stimulation. Recent investigations thus tend more

and more to bring the emptying of the stomach into line with the other peristaltic phenomena of the alimentary tract, stimulation at any point producing contraction or increased tension above and relaxation below, in accordance with the observations of Bayliss and Starling⁶² on the movements of the intestine. Every tonic phase of the pylorus and the pars pylorica must, however, be followed by a phase of relaxation which, in the later phases of a meal especially, allows fluid regurgitation into the stomach and a lowering of gastric acidity. Probably a rise in intra-duodenal tension synchronises with the fall in intra-gastric tension. Although both in life and after death the aperture of the pyloric valve is a

image a normal or exaggerated tonic contraction of the whole of the pars pylorica of the stomach.

SUMMARY.

1. The present position of our knowledge relating to normal gastric sensibility, motility, and secretion in man has been reviewed.

2. Evidence has been adduced to show that the motor or muscular functions of the stomach play a far more important part in controlling both sensibility and digestion than do the secretory functions.

3. The "clinical," radiographic, and chemical criteria of healthy motor function have been briefly

CHART 7.

Tea and milk (half pint). The straight line represents total acidity and the dotted line free HCl.

very narrow one, it is doubtful whether in health it can ever be regarded as completely shut. Screening and radiograms after a barium meal suggest (even in conditions such as duodenal ulcer, which are supposed to be associated with pylorospasm) that closure can never be more than a momentary affair, for direct continuity between the gastric and duodenal shadows is so commonly visible. It is obvious that the pyloric sphincter is able to resist the passage of large fragments and semi-solid chyme, but it would also seem that it allows a more or less continuous tidal interchange of fluid contents regulated by the varying pressures within the pars pylorica and the duodenum. That such an interchange is taking place is strongly suggested by inspections of the specimens obtained by the fractional method, whether during digestion or in interprandial periods. These may reveal bile or no bile at such comparatively short intervals of time (sometimes in one half of a specimen and not in the other) that the impression is obtained of a "to-and-fro" mechanism of this kind. Without such a "to-and-fro" mechanism neutralisation could hardly be such a regular process as it is shown to be. The fact that bile becomes plentiful towards the end of a meal when the stomach is adapting itself to its diminished content and tonus is presumably increasing necessitates the conception that even at this stage the intra-gastric tension must automatically and frequently fall below the intra-duodenal tension.

I think we may fairly conclude that a reciprocal action as between the tonus of the pars pylorica and the duodenum plays a more important part in regulating (1) fluid outflow and (2) gastric acidity than the opening and shutting of the pyloric valve, and that when we speak in a general way of closure of the pylorus and in pathological conditions of "pylorospasm" we should include in our mental

image a normal or exaggerated tonic contraction of the whole of the pars pylorica of the stomach.

described. The emptying-rate for the individual with a standard test-meal shows considerable constancy, and whether in the individual or the community is a less variable quantity than acidity or tonus.

4. The variations in tonus and peristaltic activity are as wide as the variations in appetite and hunger. Extraordinary variations in acidity also occur, from complete "achlorhydria" to extreme "hyperchlorhydria," and are generally expressions of the variations in tonus, peristalsis, and motility. An appreciation of the existence of such variability in health is essential for the study of the gastric responses to disease.

5. Evidence for a correlation between physical type or habitus on the one hand and motor and secretory type on the other has been cited. A familiarity with the characters of the extreme physiological types is essential for the study of certain pathological types. In these characters may originate the liability to certain dyspeptic reactions, and possibly also the "diathesis" or liability to "retain" or to "develop" certain types of local disease.

6. Recent views on the functions and control of the pylorus have been discussed.

Milroy Lectures

ON

EPIDEMIC DISEASES OF THE CENTRAL NERVOUS SYSTEM.

Delivered before the Royal College of Physicians of London on March 5th, 10th, and 12th, 1925,

By ARTHUR SALUSBURY MACNALT, M.A.,
M.D. Oxf.,

A MEDICAL OFFICER OF THE MINISTRY OF HEALTH; EXAMINER
IN PUBLIC HEALTH IN THE UNIVERSITY OF OXFORD.

LECTURE III.*—THE EPIDEMIOLOGY OF ENCEPHALITIS LETHARGICA.

HISTORY OF THE DISEASE.

IT is possible, and even by some considered more than probable, that outbreaks of encephalitis lethargica occurred prior to 1916-17. Crookshank¹ gives an account of epidemics in the past which may have been examples of the disease, and Hall² has assembled interesting clinical evidence on the subject. It is indisputable, however, that the authentic study of the malady began in the winter of 1916-17 when von Economo³ and von Wiesner⁴ in Vienna described the clinical and pathological features of 13 cases presenting the cardinal phenomena of stupor, accompanied by disturbances of the ocular muscles.

Encephalitis lethargica next made its appearance in France, where the outbreak was studied by Netter.⁵ In March and April, 1918, a number of cases of an obscure disease, characterised usually by stupor or lethargy and ophthalmoplegia, were reported in England. Early attention was directed to the subject by Harris⁶ and by Hall.⁷ A likeness to the clinical description of botulism was observed in these cases, and the suggestion hazarded that they were due to the consumption of food infected with the *Bacillus botulinus*. A detailed investigation was made under the auspices of the Local Government

Board and the Medical Research Council which put botulism out of court as responsible for the outbreak. It should be remarked that owing to the war we were ignorant of von Economo's work, and that the disease was investigated *de novo* in this country.

The outbreak was studied from the pathological aspect by McIntosh and Marinesco, from the epidemiological standpoint by James, and by myself from the clinical point of view.⁸ We arrived independently at the same conclusion that the "new disease" was anatomically and clinically distinct from analogous affections such as the cerebral form of poliomyelitis (polioencephalitis), and constituted a clinical entity. Kinnier Wilson⁹ and Buzzard¹⁰ also early adduced evidence supporting the same conclusion. Later, we were in a position to add that the illness as it appeared in the outbreak was identical with encephalitis lethargica, described by von Economo and by Netter. Our findings were recorded in a special report to the Local Government Board, published in 1918.⁸ Since then information has been given from all quarters of the globe. A comprehensive report by Dr. A. C. Parsons,¹¹ which embodied much additional information, was published by the Ministry of Health in 1922. The more recent researches upon the pathology of the disease have been carried out by McIntosh and Turnbull, Greenfield and Da Fano and Ingleby in this country, in France by Levaditi and Harvier, and in the United States by Loewe, Hirschfeld and Strauss, Thalheimer and Amoss.¹² Buzzard, Hall, and Netter have continued to enrich our clinical knowledge, and in epidemiological investigations mention must be made especially of the work of Parsons and of Stallybrass.¹³

Encephalitis Lethargica in Great Britain.—The outbreak in 1918 affected in all some 51 sanitary districts in England and Wales. Encephalitis lethargica was made compulsorily notifiable in England and Wales on Jan. 1st, 1919, and from that date fairly complete records of all recognised cases are available. There was a recrudescence of the disease in the early part of 1919 when the notifications reached a maximum figure of 41 in the week ending Feb. 8th. Since then annual returns have shown that it has a tendency to recur in epidemic form in the early months of the year. Previously to 1924, the most considerable outbreak occurred in the spring of 1921, when a maximum of 138 notifications was reached in the week ending

* Lectures I. and II. appeared in THE LANCET of March 7th and 14th respectively.

Jan. 5th. In inter-epidemic periods the notifications have averaged about 10 per week. The outbreak in 1924 began in the latter part of January and was at first localised in Lancashire; it is noteworthy that the disease first appeared in outlying districts and only later converged on the larger centres of population. The peak of the epidemic in Lancashire was reached in the week ending March 8th, when a total of 78 cases was notified, 29 of which were in Manchester. Liverpool was affected somewhat later. From Lancashire the stress of the epidemic passed eastward to Yorkshire, and at the same time the disease began to manifest itself in Northumberland, Warwick (with special incidence on Birmingham), Gloucester (where Bristol was specially attacked), and London. The chief centres of infection were Manchester, Sheffield, Birmingham, and Bristol. Elsewhere the disease has been widely scattered and sporadic in appearance. For the first 20 weeks of 1924, 2469 cases were notified, as compared with 1155 in the corresponding period of 1921.†

The number of cases notified in 1924 up to Oct. 25th was 4605; already by this date the number of cases of the disease in 1924 had exceeded the figures for each preceding year of notification.†

Scotland.—Encephalitis lethargica is not generally notifiable in Scotland except in certain districts locally under the Infectious Disease (Notification) Act, 1889. The annual reports of the Scottish Board of Health indicate that the disease did not manifest itself in pronounced epidemic form in Scotland until 1923, when cases were reported by medical officers of health of widely different areas, both populous industrial districts and rural areas, such as Easter Ross and Aberdeenshire. There was an intensive outbreak in Glasgow in this year, comprehending 125 cases out of the 189 cases in Scotland coming to the notice of the Central Health Authority. Chalmers and Macgregor^{14 15} have reported fully on it. From the Registrar's returns it appears that in 1923, 79 deaths from the disease took place in the 16 larger towns of Scotland.

Ireland.—Encephalitis lethargica does not seem to have been unduly prevalent in Ireland, although since 1919 a certain number of cases have been reported annually from different parts. Lumsden,¹⁶ writing in 1920, had then observed some 20 or 30 cases in Dublin.

Geographical Distribution.

It is probable that instances of encephalitis lethargica occurred immediately prior to the Austrian outbreak. Examples were reported in France during the winters of 1915-16 and 1916-17 in the districts around Commercy, Verdun, and Bar-le-Duc, and came under Cruchet's¹⁷ observation in various military neurological clinics. In Austria cases were seen in the later months of 1916 and the first quarter of 1917. The outbreak subsided. In the first quarter of 1918 the disease appeared simultaneously in England and France, in Algiers, where it was probably conveyed by French troops, and in Germany in Berlin. The outbreak appears to have been restricted to the countries named. In September and October, 1918, encephalitis lethargica appeared in the United States, and cases occurred in New York, Chicago, and elsewhere.

In the first quarter of 1919 the disease was again prevalent in England and France; it also was manifest in the Netherlands, Germany, Warsaw, Italy, Sweden, and parts of Russia (Ukraine). Isolated cases were noted at Geneva and Neuchâtel in the early part of the year; later the disease prevailed in Switzerland, and examples were reported so far afield as the Philippines, Guatemala, &c. In the last quarter of 1919 it had spread to Canada (where an outbreak was recorded at Winnipeg by Boyd¹⁸), Italy, and India. During the winter of 1919-20 there was a sudden and severe outburst of the disease in Northern Italy, Austria, Bohemia, and Bavaria were also

smitten. The disease continued to occur in Germany, Belgium, and Holland, and became established in Spain and Portugal. In 1920 the Scandinavian countries were invaded. Sweden, Norway, Denmark, and Finland were appreciably affected. Cases were also reported from Bagdad, Palestine, Egypt, and China. In December, 1921, there was an outbreak of the disease in Berlin; in France the epidemic was severe. Encephalitis lethargica has appeared in Luxemburg, Roumania, Czecho-Slovakia, Malta, and Syria; cases are accumulating in the Orange River Colony and South Africa generally and have also been reported from Swaziland and the Gold Coast. Australia, New Zealand, and Tasmania are not exempt. In the New World epidemic encephalitis now occurs annually in Canada and the United States; it has appeared in some of the larger cities of Mexico, Brazil, and Chile. In 1924 a severe outbreak of an epidemic cerebral disease apparently resembling encephalitis lethargica was reported from Japan. Exercising its severest stress in Europe, its apparent birthplace, within seven years encephalitis lethargica has become widespread in every continent.

Incidence.

The number of cases notified in England and Wales annually since 1919 are given in Table I. (Lecture I.). It is probable that this under-rates the extent of the disease as many mild and abortive cases, including cases of epidemic hiccup, fail to be notified. The general attack-rate in 1920 in England and Wales was estimated at 0.02 per 1000 of the population. For London the general attack-rate was taken as 0.03 per 1000 of the population. There is not always a strict correlation between population and case-incidence in encephalitis lethargica. Bristol's aggregate of 108 cases during the period from Jan. 1st, 1919, to Sept. 30th, 1921, was nearly double that of Birmingham, although its population is scarcely half that of the Midland town. The incidence of the disease in this country shows a perceptible increase, considerably marked in 1924.

Incidence in Urban and Rural Communities.—Encephalitis lethargica has been reported chiefly from urban districts, which in 1920 supplied 86.8 per cent. of the total number of cases notified. Large cities and industrial centres have been particularly affected, probably on account of the enhanced opportunities for the spread of personal infection, although possibly the better facilities for medical diagnosis possessed by large towns may also contribute. During the three years, 1919, 1920, and 1921, examples were notified from 520 (45.7 per cent.) of the 1138 urban and from 254 (39.0 per cent.) of the 650 rural districts in England and Wales. In 1918 I found a restricted topographical distribution of cases of encephalitis lethargica in certain districts, notably in Stoke-upon-Trent. The same tendency for examples of the disease to clump in certain areas of a town or city was noted in 1924 in Sheffield and elsewhere, probably associated with density of population and increased opportunities for case-to-case infection.

Mortality.

In 1918, in the first outbreak in this country, out of 168 cases of the disease 37 died, a case-mortality of 22.0 per cent. Variant case-mortality rates are quoted by Parsons¹¹ ranging from 53.0 per cent. (McClure) to 15.7 per cent. (Bramwell). The notification figures (England and Wales) for 1919-23 gave a case-mortality rate of 54.0 per cent. In view of the failure to notify cases of epidemic nervous disease generally, and through failure to recognise mild non-fatal types of encephalitis lethargica, these figures cannot be taken as a true estimate of the number of deaths that occur among persons attacked by encephalitis lethargica. No definite opinion can be expressed at present as to the case-mortality, except that it is probably under 50 per cent.

Age, Sex, and Race.

All ages may be attacked from the newborn babe to the octogenarian. A woman of 84 has died from

† These are only provisional figures; the complete returns for 1924 are not yet available.

the disease. The main incidence of the disease begins to be apparent in those approaching adult life; 25 per cent. of a series of British cases occurred in persons between the ages of 10 and 20 years. The incidence appears to be fairly evenly distributed over the years 20 to 40, but the tendency to acquire encephalitis lethargica declines with advancing age.

Sex.—The records of the Ministry of Health show that the sexes are equally affected. Of 1273 cases, 634 were males and 639 females. This proportion is evenly maintained at different age-periods.

Race.—With few exceptions no special racial incidence has been observed. In Warsaw the case-incidence in the Jewish population was high. Butt reports that the mortality among South African natives was exceptionally higher than that of the whites.

Seasonal Prevalence.

The first outbreak occurred during the first quarter of 1918. James early called attention to the difference between the seasonal incidence of the disease and that of poliomyelitis. Since then the increase in the number of cases in the colder months of the year has been annually noted in this country, the rest of Europe, and in North America. The increase in the incidence of encephalitis lethargica usually begins towards the end of December and continues during the first quarter of the new year. The second quarter shows still many cases, but by the end of May the epidemic has waned and much fewer cases, as a rule, are notified in the third and fourth quarters of the year.

The seasonal incidence in England in 1920 was exceptional in that there was a recrudescence in May, June, and July which reached its climax about midsummer. The cause of this is not clear, but the month of July that year was abnormally wet and cold. Small localised outbreaks have occurred in non-epidemic months, for example, the Derby outbreak in a girls' home in August, 1919.

Predisposing Causes.

Careful inquiries have been made by the Ministry of Health into possible predisposing causes but little of value has resulted from the quest. The influence of pregnancy is regarded as of importance by some writers. Jorge, in reviewing a series of 18 pregnant cases, found that the mortality-rate was 72 per cent. On the other hand, the Ministry's figures show that the mortality-rate in respect of all the cases of encephalitis lethargica which were associated with a pregnancy past or present is 44 per cent.; this percentage also represents the general case mortality among all women between the ages of 20 and 40 who contracted the disease during 1919 and 1920. Social conditions appear to exert no influence upon the disease. As regards occupation, from a study of 1070 patients, Parsons¹¹ found that 734 followed indoor occupations, 133 engaged in outdoor occupations, while 203 patients belonged to an indeterminate group. He concludes that the disease chiefly attacks those who spend the greater part of the day indoors in pursuit of their avocations. Over-work is often assigned as a predisposing cause. The specific infectious diseases and diseases generally do not appear to dispose to the disease beyond the circumstance that any antecedent or associated disease may lower the patient's resisting powers to infection.

The Question of Reinfection.

It is impossible at present to say whether the disease may occur more than once in the same individual. Netter¹⁰ reports the case of a child, aged 9 years, who became the subject of encephalitis lethargica in December, 1920. The child had been in contact with a person who had suffered from encephalitis lethargica eight months previously, had apparently recovered, and then manifested symptoms of the disease again shortly before the child was attacked. G. E. Price²⁰ records a case in a girl of 12 years in whom there was one and a half

years of apparently complete recovery; then a recurrence ending fatally took place. Buzzard²¹ has seen a case of encephalitis lethargica in an elderly woman who similarly made an apparently complete recovery; four years later, in 1924, at the height of the epidemic period, she again displayed symptoms of encephalitis lethargica and died. In view of the epidemicity prevailing at the time of the second manifestation, Buzzard's case may have been one of reinfection. On the other hand, the frequent occurrence of sequelæ, mental changes, symptomatic paralysis agitans and the like, may be due to persistence of the virus of the disease which, like the virus of syphilis, may be capable of lurking quiescent in the body for long periods and of returning to activity from time to time. Hall² states there is no *a priori* reason why the virus should not so persist for any period, indeed for the remainder of life. Nonne²² believes that there may be a "normal" interval of three to four years between the acute and chronic stages of the disease. The lapse of time alone can solve the problem. Alarming from the epidemiological standpoint is the view that the virus so persisting may for an indefinite time be capable of transmission to others under fostering conditions. Netter²³ and others have adduced a certain amount of evidence in support of this contention.

Route of Infection.

Like cerebro-spinal fever and acute poliomyelitis, it seems reasonable to conclude that the virus of encephalitis lethargica first infects the upper respiratory passages, where it may either lurk and give rise to the carrier phase in the person infected or may pass on to attack the brain. There is no definite catarrhal stage associated with its early manifestations, but sore-throat is a frequent concomitant. Dr. Willoughby Gardner¹¹ has described its peculiar characteristics thus: "There is slight swelling but very marked congestion of the fauces and pharynx; the colour is generally a deep crimson, but sometimes is almost vermilion. There is comparatively little swelling of the tonsils, but whitish patches of exudation are to be seen on tonsils, fauces and pharynx. . . . These throats tend soon to become dry, and are often associated with a red, bare, swollen, and dryish tongue." Similar attacks of "sore-throat" are seen in the associated abortive and mild cases. I was especially struck by this in the mild cases in the Derby outbreak. There is reason also to believe that the virus may enter the brain through the eyes. I early drew attention to the frequent presence of conjunctivitis in the first stages of encephalitis lethargica.⁸ Levaditi, Harvier, and Nicolau's²⁴ experimental method of transmitting the virus of encephalitis lethargica in series in rabbits by corneal inoculations is of interest in this connexion.

Lastly, infection by the gastro-intestinal route cannot be dismissed. Many cases of illness in the 1924 epidemic associated with undoubted cases of encephalitis lethargica exhibited vomiting and diarrhoea. Exactly as in poliomyelitis, a gastro-intestinal type is recognised in the mild and abortive forms of encephalitis. Gastro-intestinal symptoms occur occasionally in the disease, and in autopsies on patients in 1924 presenting these features ulcers were observed in the intestine together with softening and slight enlargement of the spleen. In 1918 in the first post-mortem I performed on a case of encephalitis lethargica this splenic condition was noted.

Incubation Period.

No definite statement can be made as to the incubation period. It is probably variable like that of acute poliomyelitis. Reece's²⁵ case of a nurse infected by a patient would assign the incubation period as nine days. In the fulminating outbreak at Derby the incubation period may have been of short duration. Our records at the Ministry of Health suggest that it may vary widely from one to two days up to two weeks or more. Kling and Liljenquist²⁶ found the period could be determined in three of their cases and regard it as being ten days. Five

days is the duration of incubation, according to Godfrey and Gwyn.²⁷ For the isolation of persons who have been in intimate contact with the disease three weeks is usually regarded as sufficient. Most recorded cases assigned to direct contagion have developed the disease within this period.

Epidemic Hiccup.

Von Economo³ recorded hiccup as a complication of encephalitis lethargica in one of his original fatal cases in 1917, and I noted it in five of my series of cases in 1918.⁸ In the autumn of 1919 small outbreaks of illness occurred in Egypt, Austria, Italy, Germany, and Canada in which hiccup, sometimes associated with fever, was the predominant symptom. In 1920-21 it was particularly prevalent in France. Railliet²⁸ saw 130 examples at Rheims in November and December, 1920. At the same time epidemic hiccup appeared in this country and was investigated by Farrar and myself on behalf of the Ministry of Health.¹¹ It is contagious—the casualty medical officer of Charing Cross Hospital apparently contracted it from his patients—though not in a high degree. In the first quarter of 1924 epidemic hiccup was widespread. It was seen in definite association, for instance, in the same household, with encephalitis lethargica; an attack of hiccup may precede or accompany the nervous symptoms of the major disease and there is strong reason, in view of the cumulative evidence, for regarding epidemic hiccup as a mild or frustrated form of encephalitis lethargica.

PREVENTION OF EPIDEMIC DISEASES OF THE CENTRAL NERVOUS SYSTEM.

The first step in prevention of disease is to survey the magnitude of the problem. It has been shown in these lectures how defective is notification of epidemic diseases of the central nervous system, and it is incumbent upon both medical officers of health and practitioners of medicine to aim at improvement in this respect, and, particularly in epidemic periods, to keep an alert watch for abortive and mild types of nervous disease.

Health authorities in epidemic periods should endeavour to inform the public, by means of leaflets, posters, notices in the press, cinema films (preferably shown in the open), lectures in the school, &c., how infection may be guarded against and the care to be observed in case of attack. Public information should be circulated also respecting the local facilities for treating patients which have been provided in the district. When epidemics prevail, all crowded assemblies should be discouraged, as far as is possible, and all gatherings of young children must be avoided; young children must not be allowed to enter any house where there is a case of illness. The latter precautions are of especial importance in outbreaks of poliomyelitis.

In view of the severity of epidemic nervous diseases and the value of good nursing for the patients, it is important to secure hospital treatment as far as possible. The isolation hospitals of local authorities are often available for this purpose. In addition, any public nursing arrangements possessed by or arranged with the authority should be made available for patients treated at home. In the case of patients so treated the sick should be isolated from the healthy, the association with other inmates of the household being limited to what is necessary for requisite care and nursing.

School-children in the affected household may be kept from school, as a precautionary measure, for three weeks after the isolation of the patient. There is no necessity to place restriction on the movements of other occupants provided they are frequently examined and remain well. Those in contact with the case, however, may be advised to use antiseptic nasal sprays or douches and to gargle the throat. Any person in the infected household who suffers from sore-throat or other symptoms suggesting an abortive attack should be treated from this point

of view and isolated as far as possible until they have recovered. The sick-room should be thoroughly cleansed and disinfected at the end of the illness.

In only one of the three epidemic nervous diseases does the question of serum-therapy at present arise as a prophylactic measure. So far the experience with prophylactic injections of anti-meningococcal serum has not given such favourable results as to commend its general adoption in an epidemic period of cerebro-spinal fever.

GENERAL FEATURES OF EPIDEMIC DISEASES OF THE CENTRAL NERVOUS SYSTEM.

It is apparent from our study of the epidemiology that the three diseases, cerebro-spinal fever, acute poliomyelitis, and encephalitis lethargica, all possess points of similarity. So much is this the case that the clinician may find it hard to make a differential diagnosis; epidemics of cerebro-spinal meningitis have frequently been confounded in the past with those of acute poliomyelitis, and acute poliomyelitis, especially in outbreaks where cerebral types occur, has been mistaken for cerebro-spinal fever. Encephalitis lethargica when it first appeared, after the diagnosis of botulism had been excluded, was considered a cerebral form of poliomyelitis. Osler for a time held this view. The advocates of the epidemic constitution hypothesis would correlate all three epidemic diseases of the central nervous system as manifestations in the wake of influenza.

In these lectures the view has been adopted, from epidemiological, clinical, and pathological evidence, that each of the diseases considered is an independent entity. At the same time the resemblances indicate that they belong to the same epidemiological family tree, and repeated allusion has been made to the fact that the study of one disease may make clear the epidemic behaviour of the others. Elsewhere, I have compared the relation which subsists, for example, between acute poliomyelitis and encephalitis lethargica to that between typhoid and paratyphoid fevers.

GENERAL BEHAVIOUR OF EPIDEMICS OF THE CENTRAL NERVOUS SYSTEM.

It has been mentioned that cerebro-spinal fever occurs in epidemic periods or cycles, and suggested that acute poliomyelitis and encephalitis lethargica also obey an epidemic law of this character. The organisms of epidemic nervous disease are always present in countries which have been affected by previous outbreaks of these diseases. This is shown by the presence of sporadic cases as well as by bacteriological evidence which indicates that persons may harbour the meningococcus or the virus of poliomyelitis in non-epidemic periods without displaying symptoms of illness. By these means the strains of the causal organisms are kept in circulation through a community. Consideration has also been paid to the question of evolution of these organisms which, previously mere saprophytes, may to-day have assumed inimical parasitical characteristics. It has further been contended that the central nervous system of man to-day is more subjected to fatigue and strain than in more leisured centuries, and that the organisms have attacked him in a region where his systemic defences are weakest.

It is at this stage that some factors as yet unknown come into play and initiate an epidemic of nervous disease. The virus of the disease is exalted, possibly by increasingly frequent passage through susceptible individuals; the increasing number of cases in successive years which portend an epidemic is in favour of this contention possibly by cosmic influences, such as unusual variations in seasonal temperature, excessive warm weather, and the like; probably other factors appear simultaneously, which lower the defensive forces of the human organism, and to these may be added increased opportunities for personal infection to the influence of which the movements and aggregation of troops in the last war supply ample testimony.

Infection in a nervous epidemic is disseminated, in the first place, like other infectious diseases, by case-to-case contact. If this method of propagation always succeeded, epidemics of nervous disease would be the deadliest of all scourges of mankind. Personal contact does not play the major rôle in the epidemic spread, although, in my own view, its influence is greater than that commonly assigned to it.

The links in the chain of infection are broken, first, by the fact that the causal organisms die out quickly and have a brief existence outside the body; second, because many persons infected do not contract the disease owing to lack of that mysterious catalytic agent of infection which is termed susceptibility. While these epidemiological characters stand to the credit account of epidemic nervous diseases, others must be debited which are important and serious, and make the problem of prevention extremely complex and baffling.

It may be assumed that in epidemic periods the viruses of these diseases are widespread among the population of the area affected. The thesis, as we have seen, is proven for cerebro-spinal fever and acute poliomyelitis. The epidemiological behaviour of encephalitis lethargica bears so great a resemblance to these diseases that the assumption appears equally true for it also, although at present bacteriological proof cannot be adduced. There is reason for postulating that any one of the "carriers" may transmit epidemic nervous disease to others, or may more rarely themselves develop a declared type of nervous illness. In these diseases there is as yet no method of animal experiment, as in the case of diphtheria, for deciding whether the "carrier" harbours a benign or virulent form of organism. Furthermore, all three forms resemble one another in that they give rise to mild and abortive types which often pass unrecognised and which have all the potentialities of disseminating the epidemics in their gravest form. I would submit that it is these circumstances which underlie the widespread distribution of an epidemic and its apparent sporadicity. It has been noted by Wickman and others that when an epidemic of nervous disease is localised and restricted to a particular town or small district the channels of direct and indirect infection from individual to individual can be traced with almost mathematical exactitude.

A last common characteristic of epidemic nervous diseases, and the most encouraging one yet cited, is that they conform to the behaviour of other epidemics in waning as well as waxing; they are all much influenced in this respect by seasonal variations.

EPIDEMIOLOGICAL DIFFERENCES BETWEEN EPIDEMIC DISEASES OF THE CENTRAL NERVOUS SYSTEM.

We have arrived at the conclusion that all three epidemic nervous diseases here considered resemble one another in epidemic behaviour in certain general features. It is equally well established that they possess distinct and independent epidemiological characters. The most important points of difference are seen in age-incidence, mortality, and seasonal incidence.

Table V. illustrates the differences in age-incidence shown by the three diseases. The greatest incidence of cerebro-spinal fever is at the 5-10 years age-period, that of acute poliomyelitis under 5 years of age, and that of encephalitis lethargica at the middle period of life.

Concerning mortality in both sexes, the fatality per cent. for epidemic nervous diseases in England and Wales for the year 1919 was found to be as follows in each disease: cerebro-spinal fever, 67.2 per cent.; acute poliomyelitis, 14.7 per cent.; encephalitis lethargica, 54.6 per cent.

As regards seasonal incidence for the year 1919, the highest point occurs for cerebro-spinal fever in May, for acute poliomyelitis in September, and for

encephalitis lethargica in January. There are also many minor points of epidemiological differentiation which have been already set forth.

TABLE V.—Showing for 1919 in England and Wales the Attacks by Cerebro-spinal Fever, Acute Poliomyelitis, and Encephalitis Lethargica at Different Age-periods as Percentages of Total Attacks at all Ages (Civil Population Only).

Year 1919.	Both sexes.						
	Under 1.	1-	5-	10-	15-	20-	30 +
C.-S.F. ..	10.36	16.06	18.26	15.28	15.82	10.88	13.34
A.P. ..	6.49	46.01	25.04	11.13	6.12	3.34	1.87
E.L. ..	1.53	5.92	7.63	10.69	13.93	14.50	45.80

C.-S.F. = Cerebro-spinal fever. A.P. = Acute poliomyelitis.
E.L. = Encephalitis lethargica.

CONCLUSION.

It sometimes falls to the lot of the epidemiologist to play the ungrateful part of Cassandra. In 1919, when writing of encephalitis lethargica, I drew attention to the infectivity and increasing number of cases of that disease and hazarded the opinion on the analogy of acute poliomyelitis that succeeding years might see a wider distribution of the disease in epidemic form. To my regret that prophecy has been fulfilled.

I am reluctant to seat myself again on the Delphic tripod, but the purpose of these lectures would be incomplete if attention were not again drawn specifically to the increase in epidemic nervous diseases, as displayed in recent years, an increase which the notification figures of England and Wales indicate but which must fall short of the true magnitude.

As regards cerebro-spinal fever, the notification figures since 1918 show a pleasing diminution; it is therefore to be hoped that we are now well towards the end of the epidemic period.

The prevalence of acute poliomyelitis continues and is an unwelcome portent. Still less reassuring is the increased epidemicity of encephalitis lethargica, and when thought is taken for the numerous mild and abortive forms and the many cases of epidemic hiccup which do not appear in the notification returns the increase becomes positively alarming.

It must be remembered that the mildest form of epidemic encephalitis may be followed by the most serious after-effects which cripple the individual concerned for life, either mentally or physically. The way in which epidemic nervous diseases are transmitted, above all the existence of the healthy carrier, makes, as has been shown, the application of the ordinary administrative measures employed for limiting epidemics of ordinary acute infectious disease to a large extent nugatory. Certain preventive measures that may be of service have already been considered.

At the same time the disciple of preventive medicine cannot stand aside, unfaithful to the high traditions of his calling, and watch the progress of epidemic nervous disease unmoved, until such time as the bacteriologist or biochemist supplies a serum or chemical compound to cope with the active virus. The one ray of light in this cloud of epidemicity is the fact that many persons are known to be insusceptible to infection. In the case of poliomyelitis Amoss and Taylor²⁹ have shown that certain bodies exist in the nasal secretions of certain individuals which are protective against the virus of that disease. If these protective substances are rarely found or are absent in young children the circumstance may account for the stress of the disease on the younger ages.

It may be suggested, therefore, that a closer study of the problem of susceptibility to infection may be an important means of acquiring success in coping with epidemic diseases of the central nervous system, and that the epidemiologist will do well to explore this avenue of research in the company of the clinician and the bacteriologist.

LIME DERMATITIS.

By W. J. O'DONOVAN, M.D., M.R.C.P. LOND.,
CHIEF ASSISTANT, DERMATOLOGICAL DEPARTMENT,
LONDON HOSPITAL.

BOTH the mechanical and chemical sides of modern factory life are a fertile ground for new and increasing hazards to health. Old industries suddenly multiply or extend, alterations in factory processes bring in risks unrevealed by a consideration only of the chemical composition of the finished product. I wish here to show that a fuller consideration of the ill-effects of lime upon the skin is not only overdue, but that it affects a far wider industrial population than was envisaged by the leading dermatologists of the last generation.

Lime or cement is not mentioned in the index of the late Sir Malcolm Morris's text-book,¹ although in the chapter on eczema he states, "that it is by no means uncommon to see artificial dermatitis on a bricklayer's hands, followed by the development of true eczema on parts of the skin that have never been in contact with lime."

No paper on lime dermatitis has appeared in the *British Journal of Dermatology*. Prosser White² mentions that lime holes are found in the hands of pullers who scrape off hair from lime-soaked skins. Plasterers, masons, whitewashers, bricklayers, and cement-workers suffer, he says, from an eruption caused by splashes when slaking lime, in mixing Roman cement, and from the presence of lime dust,³ and he pictures the deformed nails of a plasterer. Nevertheless, there is need of an authoritative record of observed cases first to establish the modern frequency and severity of lime dermatitis, and second, for reference by any medical practitioner who may be subpoenaed to give evidence in such cases under the Workmen's Compensation Acts. The need for work along this line is stressed by Dr. Macleod in his text-book of 1920.⁴

There are underlying group resemblances between cases of industrial dermatitis of diverse origin, but when the stage has been reached when the dermatitis of a chrysanthemum grower can be distinguished at sight from that of a hop-picker, and that of an arsenic-worker from that of a pitch-breaker, it will be conceded that a close study of case-records is essential if diagnosis is to progress beyond the recognition of the action of an undefined external skin irritant. In analysing these cases the patients themselves can often give

little help owing to a congenital obtuseness or to the fact that the accepted title of their calling may be actually misleading.

Industrial Expansion of the Lime Industry.

Scattered through the chalk hills of Kent are many lime-kilns of real antiquity. One well known to me near Molash, Ashford, has not had its fire extinguished for certainly 100 years. Lime made in this traditional method has its own peculiar dangers. Tramps know the lethal end that awaits those who lie down for warmth on the earth beside the glowing tops of the kilns that are sunk into the soil in the form of narrow brick-lined cones. Farm labourers and fruit-growers are acquainted with the burns experienced when lime-washing their fruit trees. Leather gloves are habitually worn for this work on the great fruit farms about Swanley, Kent, but these men, as did the miner (Case 4), complain of great soreness of the skin on washing after the day's work is over.

The invention of cement by Aspdin in 1824 and the invention of mechanical means of manufacturing cement have enormously widened the field of possible human contact with lime or lime products.

A comparison between the first illustration of a wind-driven cement-mill on the river Medway with the photograph of the Associated Portland Cement Manufacturers' modern plant at Burham, Kent (Figs. 1 and 2), will drive home how great is the expansion that has occurred in the use of lime since a cement-making process was patented. Such factories are to be found in many places. The Associated Portland Cement Manufacturers have most kindly informed me that the annual output of Portland cement is probably about three million tons, and that of lime of all grades less than 500,000 tons.⁵ Five thousand men are regularly employed at cement factories, and there are countless piers on the banks of the rivers Thames and Medway for their export and coastal trade. The blue lias lime referred to as being used in the London "tubes" contains so much silica that it may be regarded as a hydraulic cement.⁶

Clinical Reports.

The following cases show the influence of lime in the causation of local and of generalised grave dermatitis in various occupations. Recurrent cases of severe disabling dermatitis in which neither patient nor doctor has appreciated the true aetiology make it important that this unappreciated hazard should be reported. A special form of engineering, by no means confined to London, is the boring of underground

tunnels, with or without the aid of compressed-air shields. The men call themselves miners, or sometimes tunnel-miners, but without careful and pointed questioning it is doubtful if the causal link between the work and the disability could be determined in the consulting-room. This miners' dermatitis is a lime dermatitis. Five such cases of recurrent dermatitis have come to Dr. J. H. Sequeira's clinic this year; all have been employed in the same manner, and none volunteered any guess as to the causative factor.

CASE 1. Lime Dermatitis watched over 15 Years.—This patient (J. U.) has been three times in hospital, and the course of his industrial history is very interesting. In 1909 he was an in-patient in the London Hospital for a month and diagnosed as seborrhoeic dermatitis. Occupation: "The patient works underground and sweats considerably." He gave a month's history of an itching papular eruption on the forearms, thighs, and sternal region; the vertebral sweat furrow is free from rash. Treatment: alkaline baths, resorcin, and sulphur ointment. Discharged cured. 1911: In hospital August 31st to Oct. 2nd, with a diagnosis of exfoliative dermatitis. Occupational note: A compressed air-worker, has recently had some red-lead paint dripping

FIG. 1.

Old cement mill on the river Medway.
(By courtesy of Associated Portland Cement Manufacturers.)

from the tunnel shields on to his arms. He gave a one month's history of a red papular eruption, non-irritant, on his forearms, spreading rapidly on to arms and thighs. On admission there was a general erythrodermia and exfoliation, more marked on the face, arms, and legs. Treated by oatmeal baths, resorcin lotion, and an ointment of glycerol of lead subacetate. 1914: While working on the Post Office tunnel (as a grouter) outside the London Hospital he had a mild attack of dermatitis. As far as he can remember never acted as a grouter, except on the occasions mentioned above, and splashes of lead paint were a most unusual occurrence. 1924: Age now 47, has been a tunnel-miner for 26 years. He came to the skin out-patients' department on August 8th, 1924. All his attacks have been in the summer months, when he sweats profusely. His trouble started

about the end of May of this year. Occupational note: He has been doing grouter's work since the end of April 24th for the first time since 1914, not by intention. This work is casual piece-work, depending on the amount of tunnel engineering under construction. It consists of sealing up the space between the iron shields and the brickwork of the tunnel under construction with slaked "blue lias" lime. Lime is emptied from sacks into receptacles by the

FIG. 2.

The Associated Portland Cement Manufacturers' Works
at Burham, Kent.

grouter and conveyed by him with a hand-scoop to a tank of water. Both these operations are entirely hand processes. The lime is forced into the space by air pressure. At piece-work all work is at high pressure which increases the amount of dust formed. J. U. was working at an air pressure of 12 to 27 lb. to the square inch. After work, when home, this man cleaned by washing in soap and water with half a small spoon of soda to the gallon.

Condition on Admission (August 8th, 1924).—There were small boils and follicular pustules, discrete, but numerous, on both forearms, the legs, and a little on the hands. On the backs of the hands, on the dorsa of the feet, and around the wrists the skin was thick, dull pink, harsh, dry, finely scaling, and fissured over the knuckles. Around the neck and on the torso, arms, and thighs were numerous blotches of red skin. In and on the ear margins were adherent yellow scabs and small pink papules. The epitrochlear and axillary glands were moderately enlarged, painful, and tender. The patient's health was not really much affected; there was no fever, no sign of any visceral change, urine natural.

Differential blood count by Dr. H. A. Ash, of the Clinical Laboratory: Total white cells, 14,249 per c.mm.; poly. neutrophils, 64.5 per cent.; poly. eosinophils, 1.5 per cent.; small lymphocytes, 16.5 per cent.; large lymphocytes, 3.0 per cent.; large hyaline cells, 14.0 per cent.; coarsely granular basophils, 0.5 per cent.; Wassermann reaction positive; no leucoplakia. (Fig. 4.)

It is unique in my experience that with an account of a dermatitis extending over 15 years, recurring only when occupied on a particular process involving contact with lime, the connexion between cause and effect should never even have been suggested by the sufferer, who in this case is above the average in intelligence.

CASE 2.—A. C., aged 43, a tunnel-miner, came to Dr. Sequeira's clinic on May 10th, 1923, for a second attack of dermatitis. He said that his work was to blow lime into the casing of underground tubes. On both forearms, particularly on the hairy aspects, were many large discrete follicular pustules and scabs. The rest of the skin was unaltered in texture, there was no adenitis, the nails were unaffected. He was well in a fortnight.

CASE 3.—H. D., aged 42, has been a "miner" in tunnels for 29 years. Had a skin attack 17 years ago, and frequent attacks since. All previous attacks affected the forearms only. His present trouble started three months ago in the same sites, but has extended rapidly. On examination (Feb. 28th, 1924) his forearms were pink, dry, and scaling all over, his palms dry, thick, and hard, and his whole skin was drier than normal (ichthyosis). The skin of the scrotum and the adjacent parts of the thighs was moist, macerated, and reddened. He was treated with calamine lotion and a bromide mixture and in two months was well, save that

he had now, away from work, become more neurotic. His original lesions were gone, but he had developed pruritus and with peri-anal excoriation.

CASE 4.—W. G., aged 59, was sent to the skin clinic of the London Hospital on Oct. 14th, 1924, as a "toxic rash." By occupation he was an underground tunnel-miner and had been mixing and using "blue lias" lime for 24 years. He knew three fellow-workers affected like himself by their work. There were no facilities for washing at his job. This was his first attack, and had lasted for six weeks. The rash started on the forearms and was now widespread on the limbs and face. There was a red, oozing, and scabbed confluent rash on the forearms, most intense at the wrists, the legs a dull pink with patches of fine desquamation, there were discrete red or pink papules on the forehead, face, and trunk. There was no adenitis and no fever, no boils, the general health was unaffected. He was admitted for rest and to avoid the complications that might be set up under unfavourable home conditions. (Fig. 3.)

CASE 5. *Lime Erythrodermia*.—T. L., aged 57, has been a street mason from the age of 19, handling lime daily to make mortar. He has always had good health and, save for a few boils on the neck in the last 12 months, has had no previous skin trouble. His rash started early in July, 1924, in the form of itching red pimples on both forearms, and spread in three weeks to the thighs, head, and trunk in this order. He first came to out-patients' department on August 12th, 1924, showing then a general bright erythrodermia with scaling from his scalp to his feet with no islands of unaffected skin. He was made an in-patient on August 12th, 1924; his skin was red all over and hot to touch, it was thickened with a criss-cross exaggeration of the normal skin pattern. Desquamation was slight and was confined to the scalp and face, the feet and legs pitted on pressure. A blood examination by Dr. Ash, of the Clinical Laboratory, on

FIG. 3.

Case 4.—W. G., Scabbed and fissured erythema due to lime.

Dec. 8th, 1924, showed erythrocytes, 4,125,000; hæmoglobin, 78 per cent.; colour index, 0.98; leucocytes, 11,500 per c.mm. Stained blood: Polynuclear neutrophils, 63.5 per cent.; polynuclear eosinophiles, 6.5 per cent.; small lymphocytes, 18.5 per cent.; large lymphocytes, 2.5 per cent.; large hyaline cells, 9 per cent.

On examination I could find no physical signs of visceral disease. Examination of the C.N.S. showed an anæsthetic soft palate, insensitive sclerotics, no other abnormality. After three weeks rest in bed the colour of his skin lessened to a pink, but an evening rise of temperature to 101° F. coincided with the development of numerous boils which came out in successive crops over three weeks, after which the patient slowly and steadily recovered.

CASE 6. *Housewife's Lime Dermatitis*.—E. S., aged 32, married, a brunette, came on July 22nd, 1924, with a vesicular eruption of two weeks' standing on the backs of her hands and fingers. At the beginning it was irritating, but had now become painful. She attributed it to using chloride of lime in her washing tub. She ceased attending after a week's treatment. E. S. attended again on Dec. 2nd, 1924, with a rash on her hands, mostly the right, of four days' duration. There was a confluent vesicular outbreak, mostly on the dorsum and between the four fingers of the right hand. These vesicles were ruptured in some places, leaving red excoriated areas. The fluid in unruptured vesicles was white and opaque. On the back of the wrist and over the base of the right thumb were discrete vesicles of pin-head to millet-seed size. The right palm was sweating freely; the left hand was very much less affected, the lesions itched. There was no regional adenitis and no fever, the tongue was clean, many teeth were carious. Calamine liniment was applied and in a week all vesicles were gone, she developed no perionychia and no follicular pustules. (Fig. 5.)

S. Norman Dykes⁷ has described in a letter a case of generalised dry scaly eczema with painful fissures in a foreman "rough-caster" working in cement,

and notes his inability to find any reference to cement as a cause of occupational dermatitis. J. C. Lyth⁸ has described the case of a man, aged 38, a plasterer's labourer working chiefly in cement, who had four attacks, of increasing severity, of desquamation, at first discrete on the arms and hands, and later "both hands and forearms completely covered with a

FIG. 4.

Case 1.—J. U., Follicular pustules in a "tunnel-miner."

profusely exfoliating eczema." An unsigned letter in THE LANCET in 1917 records that Portland cement if moistened and allowed to adhere to the fingers for half an hour, blanches and shrivels the fingers, and bores pin-holes in the tips.⁹

Perforation of the Nasal Septum.

I have been unable to find any English reference to perforations of the nasal septum due to lime, but the

FIG. 5.

Case 6.—E. S., Recurrent excoriated vesicular eruption due to bleaching lime in the household washing.

following quotation, although not a case-record, is definite:—

CHAUX: Elle exerce cependant une action de brûlure sur le peau et les chauffourniers s'en garantissent en se graissant fréquemment les mains avec du suif. Ciment: La poussière de ciment, dont l'influence sur l'organisme n'est pas définie. . . . Il se produit dans le cloison nasale, à sa base, une perforation de dimension variable. . . . De plus, il est recommandé aux ouvrières d'adopter une coiffure protectrice pour empêcher l'action irritante et caustique des matières manipulées sur le cuir chevelu.¹⁰

Summary.

(1) Lime dermatitis is now to be looked for in a wide field of industrial life. (2) The patient's trade label is often a most insufficient guide to this special industrial hazard. (3) A small group of cases is recorded amongst "tunnel-miners" not hitherto reported as liable to lime dermatitis. (4) The types of dermatitis that may be seen are vesicular eruptions or cheiopompholyx, lime holes, seborrhœic eczema, exfoliative dermatitis, intertrigo, erythrodermia, pustular follicular dermatitis, and septal perforation. (5) Over-sweating or abnormal dryness of the skin are predisposing factors. (6) Preventive measures consist in frequent changes of all dust-laden under-clothing, alternation of employment on to lime-free work, and the nightly application of emollient grease to the skin of the face, hands, and forearms.

THE ÆTIOLOGY OF HÆMOPHILIA.

BY J. W. PICKERING, D.Sc. LOND.,

AND

R. J. GLADSTONE, M.D. ABERD., F.R.C.S. ENG.

(From the Departments of Physiology and Anatomy, University of London, King's College.)

THERE is no unanimity in the views which have been suggested to explain the delay in clotting of hæmophilic blood, and treatment remains empirical. Two cases are here recorded in which the characteristics of hæmophilic blood closely resembled those of embryonic blood. In both complete coagulation was produced by raising the temperature of the shed blood to 38° C., without the addition of coagulants.

Critical Summary of Previous Work on Hæmophilic and Embryonic Bloods.

Sahli¹ found that the same amount of fibrin can be obtained from both hæmophilic and normal blood. Adopting the theory of blood coagulation suggested by Morawitz,² he maintained that the delayed clotting in hæmophilia is due to a shortage of thrombokinase in the wounds of the bleeders. This opinion was supported by Morawitz and Lossen,³ who found that the addition of tissue extracts to hæmophilic blood hastened its coagulation. Nolf and Herry,⁴ however, maintained that the thrombokinase is altered in quality instead of in quantity. The deficiency theory is commonly accepted in current text-books, and Vines,⁵ in his recent review of the subject, classed hæmophilia with cystinuria and alcaptonuria as a deficiency disease, dependent on the lack of a ferment. No proof is, however, available that damaged cells or tissues contain a coagulant enzyme. Moreover, it is well known that contact with wounded tissues is not necessary for the clotting of blood, and recent work indicates that the detritus of leucocytes and blood-platelets, the supposed other sources of thrombokinase, is not an essential factor in the inception of blood coagulation (Pickering⁶). Addis⁷ found that hæmophilic blood is clotted as rapidly by thrombin as is normal blood, and that thrombin obtained from the blood of bleeders is as active a coagulant as that prepared from normal blood. He thus demonstrated that restraint of clotting in hæmophilia occurs prior to the formation of thrombin. This investigator

also concluded that in hæmophilics: (1) There is no substance in the blood which hinders the coagulant action of thrombin, an opinion supported by the researches of Hurwitz and Lucas,⁸ of Hess,¹⁰ and of Klinger.¹¹ (2) There is no deficiency of thrombokinase either in the body tissues or the formed elements of the blood. (3) Thrombin, and its mother-substance pro-thrombin, are present in normal quantities, a conclusion endorsed by the recent work of Wöhlisch,¹² who also found that the fibrinogen is normal in amount and behaviour.

Having found that the generally recognised factors in blood coagulation are present in their usual quantities, Addis suggested that the defect in hæmophilia is that a longer time is taken for the conversion of pro-thrombin into thrombin. Howell,¹³ Hurwitz and Lucas,⁹ and also Klinger¹¹ have, however, maintained that there is a deficiency of pro-thrombin, while Fiessly¹⁴ has recently asserted that there exists in both hæmophilic plasma and serum a substance which inhibits the formation of pro-thrombin. No indication of the nature of this substance is given.

Very little has been published on the coagulability of embryonic blood. More than 50 years ago, Boll¹⁵ recorded that the blood of embryo fowls does not clot before the twelfth to fourteenth day of incubation. Emmel, Levison, and Fisch¹⁶ recently noted that the blood of late pig embryos clots much more slowly than that of adult pigs, but is coagulated, at room temperatures, by the addition of calcium chloride. Finding the total calcium content is not below the normal, they concluded that the retardation of clotting is due to a deficiency of ionised calcium. Most investigators are agreed that there is no abnormality in the calcium content of typical hæmophilic blood, but Hess¹⁰ has recorded a case of sporadic hæmophilia in which there was a shortage of ionised calcium. The blood of this person, like that of the embryos, was clotted by the addition of calcium chloride.

Experiments on Embryonic Blood.

Whilst investigating the ontogeny of the plasma of embryo chicks, we have found: (1) The mixture at laboratory temperature (14°-16° C.) of the blood of eleventh-day embryos with an equal volume of freshly shed normal human blood inhibits clotting. Samples of human blood, which were completely clotted in open vessels at room temperature in five or six minutes, remained fluid for an hour after mixing with the embryonic blood, provided the mixture was made not later than 30 seconds after the withdrawal of the human blood from the circulation. When the embryonic blood was mixed with the human blood, which had been shed on glass for three minutes—i.e., just before the formation of clots—no suppression of clotting occurred. The blood of the eleventh-day chick does not clot either at room or body temperature, does not give reactions indicative of either pro-thrombin or fibrinogen, but contains material which coagulates when heated to 74°-75° C. (2) The blood of twelfth-day chicks remains fluid on glass at laboratory temperatures, but clots rapidly at 38°-40° C. It apparently contains fibrinogen, is clotted by thrombin, and is partially clotted by the addition, at room temperature, of considerable quantities of tissue or cell detritus—i.e., by the so-called thrombokinase. Clots do not, however, appear in the blood oozing from damaged blood-vessels. At laboratory temperatures a mixture of this embryonic blood with an equal volume of normal human blood clots at almost the same speed as human blood. A mixture of human blood with one and a half times its volume of the embryonic blood shows, however, some retardation of clotting. When two volumes of the embryonic blood are used the suppression of clotting is usually more marked. (3) The blood of fourteenth-day chicks remains fluid on glass at laboratory temperatures, but clots rapidly on the addition of small amounts of calcium chloride. In other respects it behaves like adult birds' blood.

When added to an equal volume of human blood it accelerates clotting.

It thus appears that material protective against the inception of clotting is developed in birds' blood prior to the development of its capacity to clot and that this material is not an anti-thrombin, as it does not restrain the later stages of clotting in which thrombin is developed. It seems that early embryonic blood differs from normal adult blood by the predominance of stable protective material.

Experiments on Hæmophilic Blood.

CASE 1.—Blood was obtained by finger puncture from a male, aged 20, who was suffering from an effusion of blood into the right knee-joint. Since childhood the patient had suffered from prolonged bleeding from small cuts and from the gums. Two of his brothers had suffered from protracted bleeding from small injuries, and one of them had died in hospital from hæmorrhage. The patient's blood exhibited the following characteristics: (1) It remained fluid in a glass vessel, at room temperatures (16° – 17° C.), for an hour. (2) At 38° C. it clotted in 8 minutes 30 seconds. The clot formed was firm and adhered to the walls of the containing vessel; it subsequently contracted and exuded serum. (3) It clotted immediately at room temperature on addition of the clot obtained by warming the hæmophilic blood. (4) It clotted in three to four minutes, at room temperature, after addition of the hæmophilic serum. (5) Mixed with an equal volume of normal human blood, immediately after the normal blood had been shed, it lengthened the clotting time of the normal blood from 6 minutes 40 seconds to 13 minutes 40 seconds. (6) When the mixing took place after the normal blood had been shed for four minutes no retardation of clotting occurred. (7) It was not clotted by the addition of an equal volume of 2 per cent. calcium chloride.

CASE 2.—Blood was similarly obtained from a male, aged 54, who suffered from periodic epistaxis and from prolonged bleeding from small cuts. Such hæmorrhages were, however, usually arrested in 15 or 20 minutes. Blood coagulation-times, taken by the method of Pickering and Hewitt,¹⁹ showed considerable variation during the two years the case was under observation, clotting being sometimes complete in 10 minutes, on other occasions occupying from 15 to 20 minutes. One brother and a maternal uncle were described as excessive bleeders; the sisters and a daughter appeared normal. At the time of the experiments here recorded complete clotting was obtained at 17° C., on glass, in 46 minutes 30 seconds. At 38° C. complete clotting on glass occurred in 6 minutes 5 seconds. The application of a wet bandage at 118° F. to a finger-cut completely prevented oozing of the blood in 9 minutes; oozing through a cold bandage continued for 20 minutes. (The room temperature was 15.5° C.) The addition of the patient's own fresh serum or blood-clot provoked clotting at room temperature in 5 and 4 minutes respectively. The mixture of equal volumes of the abnormal blood with normal human blood at 15.8° C. yielded a coagulation-time 2 minutes 40 seconds slower than that of the normal blood. When mixing was delayed until 4 minutes after the normal blood had been shed the coagulation-time was 3 minutes faster than that of the normal blood.

Discussion.

The preceding experiments show marked resemblances in the behaviour of the blood of early embryos and that of the hæmophiles investigated. Both the bloods, when added immediately to normal human blood, retard its coagulation, but neither inhibits the later stages of clotting in which thrombin appears. Blood from the severe case had greater protective power against the inception of clotting than was exhibited when the hæmophilia was less marked. Both early embryonic and hæmophilic blood are relatively stable at room temperatures and both clot in glass vessels at 38° C. Both are refractory to the coagulant action of tissue detritus (the so-called thrombokinase), and identity of behaviour occurs in all the other reactions recorded, except that the addition of small amounts of calcium chloride clots the embryonic blood as soon as its capacity to clot is developed, but does not clot the hæmophilic bloods. In this one respect the embryonic blood resembles the blood of the case of sporadic hæmophilia recorded by Hess¹⁰ and differs from typical hæmophilic blood. A probable explanation of the facts is that in hæmophilia there is either a partial persistence of an

embryonic condition of the plasma in adult life or a return to the embryonic state.

Evidence has been advanced in the papers of Pickering and his co-workers that there exists in normal circulating blood a protective colloid, which preserves the clotting complex of the plasma from change. It appears that when normal blood is in contact with surfaces which it wets, this protective colloid rapidly undergoes change and is disassociated from the clotting complex of the plasma. Prothrombin is then converted into thrombin, which converts the fibrinogen of the blood into the fibrin of clots. It has been shown by Pickering and Taylor^{17, 18} that the addition of various inert protective colloids to freshly shed blood inhibits the inception of clotting, but fails to suppress the coagulant action of thrombin on either blood or on fibrinogen. A similar condition to that of the blood in the milder case of hæmophilia has thus been produced *in vitro* by increasing the concentration of protective colloid in otherwise normal blood. The protective material of eleventh-day bird embryos appears not to undergo change in the act of bleeding, hence its addition to freshly shed blood suppresses clotting to a degree equal to that found in the severe case of hæmophilia. Hæmophilic blood only slowly changes towards clotting when shed, and the suppression of clotting apparent when it is added to normal blood is in like manner intelligible as due to the presence of an excess of a stable protective colloid.

Although the total protein content of hæmophilic serum appears to be less than that of normal blood, a globulin is present in excess (Hurwitz and Lucas⁹), and we have found that embryonic plasma at the time when it is highly protective against the clotting of adult human blood consists mostly of material which coagulates at 74° – 75° F., at the heat coagulation temperature of a globulin.

One of the most troublesome and apparently inexplicable features of hæmophilia is the continued oozing of blood through wounds which contain clots and presumably thrombin. The presence of unclotted blood bathing cuts, even at body temperature, is not, however, without parallel in experimental work. Pickering and de Souza²⁰ observed that if threads are introduced into the ventricles of a living heart, separated from the circulation by mass ligature, massive clots are formed, but some blood remains fluid. This clots immediately it is shed on glass. The fluidity of the blood in contact with clots is intelligible as due to the presence, *in vivo*, of undisturbed protective colloid; its rapid clotting when shed may be ascribed to disturbance of the protective colloid followed by the coagulant action of the thrombin present. In a similar but more marked manner the excess of protective colloid in hæmophilic blood prevents the thrombin formed in wound clots from acting on the fibrinogen of oozing blood. Similarly, an excess of protective colloid or the presence of a protective colloid of unusual stability would delay the conversion of pro-thrombin into thrombin, and there is no need to assume that the pro-thrombin of hæmophiles is either deficient in quantity or altered in quality. The coagulant action of tissue extracts on hæmophilic blood is also explicable without assuming a deficiency of "thrombokinase." The work of Pickering and Hewitt²¹ indicates that the detritus of cells and tissues disturbs the surface conditions of the plasma, and such disturbance accounts for its coagulant action on hæmophilic blood.

Summary.

(1) The hæmophilic bloods examined coagulated in 6–8 minutes at 40° C. This property may possibly be utilised in controlling oozing from wounds and epistaxis. (2) Hæmophilic plasma exhibits most of the characteristics of early embryonic plasma. (3) The protective power against clotting of both hæmophilic and embryonic blood is not due to the presence of an anti-thrombin. (4) It appears probable that the delay in the clotting of the

hæmophilic bloods examined is due to the persistence or reappearance in adult life of an embryonic condition of the plasma, and that in both hæmophilic and embryonic blood there is present a relative excess of a stable protective colloid. This conclusion is concordant with the theory of the fluidity and clotting of blood enunciated by one of us.

It is hoped that those in touch with cases of hæmophilia will communicate with us (at King's College, W.C. 2) and thus assist in this inquiry.

HÆMORRHAGE DURING DISSECTION OF THE FAUCIAL TONSILS.

A SCHEME FOR CONTROLLING THE VESSELS BEFORE DIVISION.

BY NORMAN PATTERSON, F.R.C.S. ENG.

ENUCLEATION by one method or another is now the routine practice in dealing with enlarged or septic tonsils. Each surgeon soon acquires a technique of his own, which from time to time he may modify. So long as the tonsil in its capsule is removed with as little damage as possible to the mucous membrane and muscles, and the resulting fossa is absolutely free from bleeding at the end of the operation, the procedure can be pronounced as satisfactory.

Technique.

As far as the exposure of the capsule is concerned, the technique which I adopt is much the same as that generally practised. It is important to preserve not only the pillars, but also any mucous membrane lying between the pillars and the tonsil, including the plica semilunaris. The mucous membrane is first of all divided in front, above, and behind, and the capsule exposed, keeping as close as possible to the tonsil and generally well behind the edge of the anterior and in front of the edge of the posterior pillar. The next step is the separation of the lateral part of the tonsil from the bed in which it lies, making no attempt to free either the upper or lower poles from their attachments. It is mainly in the region of the upper pole that the blood-vessels run to and from the tonsil, and an attempt even by blunt dissection to free this pole will probably result in tearing vessels with resulting hæmorrhage. When the middle portion of the tonsil in its capsule has been freed from the pharyngeal wall, the tonsil itself is drawn medially and forwards with a vulsellum. One blade of a large pair of artery forceps, which may conveniently be curved, is then passed through the opening which now exists between the capsule of the tonsil and the pharyngeal wall; the other blade of the forceps lies in front of and internal to what may for convenience be called the upper tonsil "pedicle." Half an inch or more of the blades should project beyond the clamped portion of the tissue. The tonsil is again dragged somewhat forcibly forwards and medially, and the forceps are closed, taking care that no tonsillar tissue is included between their blades. With a pair of scissors the "pedicle" is now severed on the tonsil side of the forceps. The tonsil

is then freed in a downward direction towards the base of the tongue by blunt or swab dissection. In using a metal dissector it is important to work at right angles to the plane of cleavage, and, so to speak, to tease the capsule from its surroundings. In this way bleeding is much less likely to occur. Occasionally a moderate-sized vessel will be seen and can be clamped before division. The dissection is continued in a downward direction till a "pedicle" attaching it to the tongue appears. This "pedicle" is clamped with a pair of stout artery forceps, the points passing downwards and backwards towards the epiglottis. The tonsil is cut across on its own side of the forceps. It is now only necessary to secure each "pedicle" with a ligature, and, if the points of the forceps have been left free, no difficulty will be experienced in passing this ligature.

Left side.—The tonsil is now separated and ready to be cut away.

Right side.—The ligatures are shown in position. At the end of the operation the one on the lower tonsil "pedicle" is generally out of sight.

Any redundant tissue which is present, if desired, can be cut away, but if stout forceps have been used, and if the ligature is tightly tied, the remains of the "pedicles" will slough.

Remarks.

In simple cases, if this method of removing the tonsils is adopted, there will be very little hæmorrhage since the main vessels are clamped before they are cut; there will be no danger of the ligatures slipping, as they surround substantial portions of tissue, and much time will be saved as all searching for bleeding and retracted vessels is avoided. It may not be possible to carry out this manoeuvre in every case—e.g., if the tonsil is very adherent, or its capsule partially destroyed as the result of one or more attacks of quinsy, or owing to previous and unsuccessful attempts at removal. But even in such cases the principle can be adopted of trying where possible to apply a clamp before cutting any structure that is likely to bleed. It is advisable to perform the operation deliberately, and to avoid all tearing. Any attempt at rough manipulations will be followed, most probably, by hæmorrhage, and

much time may be lost by searching for bleeding vessels after the operation is virtually completed.

The writer carries out the whole of the dissection with one instrument—namely, a pair of long blunt-pointed scissors curved on the flat.

Clinical and Laboratory Notes.

DUODENAL ULCER IN A CHILD OF TWO MONTHS.

By J. A. L. LOUDON, M.B., CH.B. EDIN.

THE following case presents some features which, in the light of the post-mortem findings, seem worthy of record.

The child, a male, was the first child of a mother aged 37. The father is 36. The labour was normal and the child weighed 6½ lb. at birth. From the first the child was difficult to rear. The breast milk was very poor in quality and quantity, and it was immediately apparent that artificial foods would have to be resorted to. The baby was accordingly put on to cow's milk and water, with added sugar, of rather under the normal strength. He was fed three-hourly.

During the first few days the child cried incessantly and had difficulty in passing urine. Circumcision was performed and thereafter the baby seemed brighter, cried less, and took his feeds satisfactorily though slowly. The stools, however, were slightly green and streaked with mucus, and there was vomiting in a mild degree of a regurgitant character. For the first month the baby put on weight very slowly. The stool varied in character from slight greenness to greenness throughout. There was always mucus present. The feeds were taken very slowly. The baby was sometimes as long as three-quarters of an hour over his feed. He cried a great deal and in any circumstances would never lie on his back without crying. He almost invariably slept for seven hours during the night without a break. The weight at the end of the first month was 7½ lb.

On account of the evident pain and the condition of the stools I decided to try glaxo. This was given, and the strength of the feeds kept below normal. The stools then assumed a brownish character and were slightly constipated. The mucus, however, entirely disappeared. The child occasionally gave a loud cry which lasted only a few moments. Weight was gradually lost; the extremities became cyanosed and the child became pinched and cried continuously even during the night. The vomiting returned after every feed, and I advised alternating feeds of albumin-water and glaxo. For a day or two there was some improvement. Pressure on the abdomen seemed to give relief to the child and he would lie contentedly enough on his stomach. After 12 days on glaxo I put the child on nothing but albumin-water for two days. There was then no sickness and very much less crying. Having had poor results with glaxo I tried Nestlé's, again in reduced strength. The result was disastrous, though I am sure any kind of food would have produced similar results. More weight was rapidly lost; the crying was incessant, and the vomiting was almost, if not quite, equivalent to the entire feed.

In despair I called in Dr. Lewis Thatcher in consultation, and on his advice the child was put on to equal parts skimmed milk and water with no added sugar. There was slight improvement for four days, and emboldened by this I added a quarter of a teaspoonful of glucose with each feed. On the third morning before the child died the stool looked suspicious. It was dark brown, constipated, and on one part of the napkin there was a hint of altered blood. The temperature was 96.4° F. in the rectum and the child was wasted. Next morning a typical melena was observed—a dark tarry stool with much almost unaltered blood. Dr. Thatcher again saw the child, who was removed to the Edinburgh Royal Hospital for Sick Children, and the same evening transfused. Another hæmorrhage occurred and the child died.

Post-mortem Examination.—On the posterior wall of the first part of the duodenum there was an acute ulcer, ½ in. in length, square, ½ cm. distant from pyloric sphincter, and having the long axis parallel with that of the bowel. The margins were clearly cut and sharply defined and there was no evident induration of the floor or edges. The floor was smooth and seemed to be formed of submucous coat, and on it several minute bleeding-points could be seen. There was a second small ulcer situated nearer the pylorus on the anterior wall of the duodenum; this affected the mucous

membrane only. There were also several mesenteric cysts containing yellowish or turbid fluid.

To Dr. J. S. Fowler, whose ward the child was in, and to Miss A. R. MacGregor, pathologist to the hospital, I am indebted for the post-mortem report. Edinburgh.

A CASE OF CEREBRAL ABSCESS COMPLICATING EMPHYEMA:

OPERATION AND RECOVERY.

By ARTHUR F. HURST, M.D. OXF., F.R.C.P. LOND.,
PHYSICIAN AND NEUROLOGIST TO GUY'S HOSPITAL.

IN THE LANCET of Jan. 17th last Mr. Seymour Barling described a case of cerebral abscess complicating abscess of the lung in which recovery followed operation, the patient being at work and in good health some months later. Although operations have been performed on a few cases of the kind before, Mr. Barling was unable to find any previous record of recovery. The following case appears therefore to be worthy of publication, particularly in view of the fact that the patient is still alive and well 13 years after the operation.

Mr. T., aged 57, consulted me on Jan. 31st, 1912. In the previous August he had had an attack of acute appendicitis, a gangrenous appendix having been removed on the second day. Seven weeks later pleurisy developed, and on Oct. 6th, 1911, an empyema was discovered and three quarts of foul pus were evacuated. The wound continued to discharge until Jan. 25th, 1912. Ever since the first operation the patient had felt very slack and disinclined to do anything for himself. He could only be persuaded with great difficulty to dress or go for a short walk. On Jan. 14th he was sick several times after supper, and his left hand and arm were drawn up, his left leg twitched, and his eyes were directed towards the left, but he did not lose consciousness. During the next three days he had hallucinations, and from this time his temper became very bad. On the 28th he dropped his cards whilst playing bridge and dropped his food on to the floor during meals, but, though dazed, he did not lose consciousness. His mental capacity was unaffected; he was quite rational when discussing business and his memory remained excellent. His temperature had been slightly raised at times ever since the first operation; it had reached 100° F. on Jan. 26th and 28th. He had complained at times of a pain on the top of his head.

On examination he was found to have complete left-sided hemianopia, with incomplete left hemianæsthesia, touch being more affected than pain. There was very slight weakness of the left arm and leg, but the left hand was extremely clumsy owing to well-marked arterognosis. The deep reflexes of the two sides were equal. The left plantar reflex was extensor, the right flexor. The left abdominal reflex was absent, the right brisk. The optic discs were normal, except for some venous engorgement. A diagnosis was made of an abscess just behind the centre of the right ascending parietal convolution. This having been confirmed by Dr. E. Farquhar Buzzard, to whom I am indebted for allowing me to see his own notes of the case, Mr. Percy Sargent operated. An abscess was found in the area indicated just below the surface, the brain substance superficial to it being red and cedematous; about two ounces of yellowish-green, foetid pus were evacuated. The abscess was drained and improvement was rapid, but was interrupted on March 24th, 1912, by an attack of acute mania, lasting ten days, just after the patient returned home.

Recovery from this was complete, and now, at the age of 70, and 13 years after the operation, he is still perfectly well in every way.

ROYAL LIVERPOOL CHILDREN'S HOSPITAL.—The annual meeting of the hospital on Feb. 26th was made the occasion of the announcement of extensive plans for extension. At the Myrtle-street city branch further accommodation for nurses and new residents' quarters are being provided, incidentally freeing space which is to be utilised for a ward devoted to accidents and minor operation cases. At the Heswall country branch a new wing is in contemplation with 60 beds. The year's expenditure was balanced as follows: Subscriptions, &c., 25 per cent.; dividends from investments, 20 per cent.; parents' contributions, 40 per cent.; the remaining 15 per cent. being deficit.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

COMBINED MEETING OF THE SECTIONS OF COMPARATIVE MEDICINE, TROPICAL DISEASES, OBSTETRICS AND GYNÆCOLOGY.

A MEETING of these combined Sections was held on March 12th, Prof. L. S. DUDGEON, President of the Section of Tropical Diseases, in the chair, when Prof. J. H. EYRE opened a special discussion on

Infective Abortion in Cattle and its Relation to Mediterranean Fever.

Prof. Eyre commented upon the relationship of the *Bacillus abortus* to the *Micrococcus melitensis*, which was so close that American observers had classified them in the same genus—*Brucella*, a method he considered cumbersome and unpractical. The clinical picture of contagious abortion in cattle, he said, was a clear-cut one. There were no premonitory symptoms till abortion took place, then a vaginal inflammation was noted, together with a discharge which contained pus cells and the specific organism; moreover, the animal which had once aborted in this manner appeared liable to do so at some future period. The path of entry of the organism appeared to be via the mouth, as a general rule, but male ruminants appeared to be carriers of the infection and thus communicated the disease during coitus. The *Micrococcus melitensis*, on the other hand, did not seem to produce any specific clinical appearances in goats; but an animal once infected with the organism remained capable of infecting others for the remainder of its life. Undulant fever in man was a very definite entity; it was a septicæmia which might run an acute or subacute course. As in goats, the path of infection was by the alimentary tract, though it might take place by inoculation. The goats themselves might be originally infected by the goat-herd and the infection was thus passed on from one animal to another. Contagion from one goat to another might also take place by sexual contact. In *Micrococcus melitensis* infection the period of incubation in the goat was about 7 days; in man 5–16 days. In freshly infected herds, he said, abortion in pregnant goats was liable to take place, while Evans, in America, had produced abortion in a cow by intravenous injection of *M. melitensis*. The speaker did not agree with American workers that the two organisms were morphologically identical. It was stated by Bang that *B. abortus* behaved like a bacillus when freshly isolated, but he (Prof. Eyre) considered that the bacillary forms which had been noted in *M. melitensis* cultures were merely involution forms, such as commonly occurred among the coccaceæ, and that these were not, as American bacteriologists asserted, the characteristic shape of the organism. Under the dark-ground illumination the behaviour of the two organisms is quite different. The correlation of the two organisms, and the diseases they produced, had arisen from a number of fortuitous circumstances; thus, Bassett-Smith originally showed that the milk of some London cows would agglutinate *M. melitensis*; but Nicolle and Conseil injected men with *B. abortus* without producing any untoward symptoms, though recently, on epidemiological grounds, Bevan had suggested that in Rhodesia undulant fever in man was due to infection with *B. abortus*; and by serological reaction Evans considered the two organisms identical.

Mr. L. E. W. BEVAN, F.R.C.V.S., whose paper was read in his absence, directed attention to his original observations published in the Transactions of the Roy. Soc. Trop. Med. and Hyg., vol. xv., No. 7, p. 230, that the serum of animals suffering from epidemic abortion would agglutinate cultures of *M. melitensis*, and he suggested that undulant fever

in Rhodesia, as it occurred in man, was in fact due to *B. abortus*, and quoted a case from Baltimore, recorded by Evans, in which the organism isolated from a human case of undulant fever was shown to be due to this organism. On the whole, he said, veterinarians did not consider the two diseases identical, mainly on the ground that milk from cows suffering from contagious abortion was used very extensively without producing any ascertainable disease in man in England; but in Southern Rhodesia a great number of cases of undulant fever in man came from districts known to be infected with contagious abortion in cattle, and the serum of these patients agglutinated *B. abortus*. Though considered by the majority of settlers to be a disease of recent introduction, he had evidence that the infection had long existed in native stock in the country. He was of the opinion that *B. abortus* and *M. melitensis* were identical and belonged to the same genus—"alkaligenes." He thought that possibly through long contact with goats and cattle the natives of Rhodesia were immune, but the first cases of undulant fever in European settlers were noted in the vicinity of Salisbury in 1921, and there were many districts where contagious abortion was common and undulant fever unknown. So far 35 human cases had been reported, 26 in men, 4 in women, and 5 in children, and the disease had occurred in all professions, not necessarily farmers. It was generally believed that the disease was contracted through infected milk, but so far no casual visitor to the country had become infected. Orpen and others had suggested that in Rhodesia the infection might be spread by biting insects. The clinical symptomatology of undulant fever in man in Rhodesia did not differ from that observed elsewhere, though it had been noted in one case that the vesiculæ seminales were affected, a complication commonly noted in bulls infected with *B. abortus*. Prophylactic measures were now being actively employed; all breeding bulls were being tested and those whose sera reacted were being removed, while heifer herds were being immunised by a specially prepared vaccine of *B. abortus*. Undulant fever in man had been declared a notifiable disease. A short addendum to this paper described the clinical symptoms of the disease in man as observed by Drs. Huggins and Howarth.

Sir P. W. BASSETT-SMITH referred to the spread of undulant fever from the Mediterranean littoral all over the world and how the infection was spread by the milk of apparently healthy animals. He had found that cows, mares, asses, and dogs were susceptible to infection, though unable for a long period to actively spread the disease. The probability was that undulant fever and contagious abortion were two separate diseases, for in Europe proper undulant fever was practically unknown, while contagious abortion had existed in our herds for a very long time. Pregnant women who contracted undulant fever occasionally did abort.

Prof. LOUISE McILROY, on the gynaecological side, spoke of her investigations on the possibility of an infective organism causing abortion in women, but her results had been entirely negative; nor were female farm and dairy workers more liable to abortion than other women. She pointed out the close similarity of the course of contagious abortion in cattle and syphilis in women.

Colonel J. C. KENNEDY, R.A.M.C., recounted some investigations he had conducted in Malta in 1914, where he had found that the serum of cows in Malta would agglutinate *M. melitensis*. As a general rule, infected goats in Malta did not abort.

Dr. J. T. DUNCAN gave a brief résumé of his work on the isolation of an organism, apparently more closely allied to *B. abortus* than *M. melitensis*, from the blood of a patient who had originally contracted undulant fever in Salisbury, Rhodesia. The patient was afebrile and had suffered from no symptoms for over a month. He considered that growth on

alkaline potato might be a means of discrimination, for on this medium *M. melitensis* formed a pigmented growth, while *B. abortus* did not.

Dr. H. HAROLD SCOTT referred to the work of Fical and Alessandrini, two Italian observers, who claimed that immune serum heated above 65° C., would differentiate the organisms, *B. abortus* being clumped above that temperature, while *M. melitensis* was not.

Mr. LESLIE SHEATH, F.R.C.V.S., considered that many of the statements made on the clinical aspects of contagious abortion were incorrect, for in his experience a large proportion of animals which did not abort were infected, while the bacillus appeared to be quite incapable of evoking any clinical symptom except during pregnancy.

Prof. EYRE and Colonel KENNEDY, in replying, terminated an interesting discussion.

SECTION OF OTOTOLOGY.

A MEETING of this Section was held on March 7th, Dr. KERR LOVE, the President, being in the chair.

Dr. T. RITCHIE RODGER (Hull) read a communication entitled

Intracranial Infection by Erosion from Subperiosteal Abscess.

The object of the paper was to show, by the narration of cases which had come into the author's experience, that suppuration was able to extend, from a subperiosteal abscess, by a circuitous route, through the outer bony covering of the cell and a re-entry through the thickness of the cranium into the brain, and erode thence at some distance from the primary focus. A typical case in illustration was the following: A girl, aged 7, was seen by Dr. Rodger in March, 1921. Four months earlier her doctor had opened an abscess over the squamous portion of the left temporal bone and evacuated some pus. The probable cause of the infection was a coincident impetigo of the scalp. Tardy healing led to the belief that the condition was tuberculous. Two months later she complained of failing vision, and bilateral optic neuritis was found to be present. A tuberculous tumour of the brain was diagnosed, and she was referred to Dr. Rodger because of meningeal signs, with high temperature, unconsciousness, and delirium, Koenig's sign being positive. The tympanic membrane on both sides was intact and normal in appearance. There had been pain in the left ear and slight discharge for one day just prior to the temporal abscess forming. Exploration revealed a temporo-sphenoidal abscess, and from it 4 oz. of pus were evacuated. This was recovered from without incident, but the vision had not improved when she left the hospital. He considered that there had been in this case an acute, short-lived mastoiditis, resulting in a subperiosteal abscess, but without gross erosion of the cortex; that the pus then tracked upwards to the squama and there produced erosion, resolution occurring in the mastoid cells and the middle ear. In another case a subperiosteal abscess had apparently formed in the floor of the frontal sinus following an acute sinusitis, but without causing any gross erosion, and the pus had tracked beyond the limits of the sinus in an inward direction. In none of the cases narrated was the subperiosteal abscess accompanied by any gross erosion of the outer cell wall. Often in such cases there was no evidence of the path of infection, and it had probably been either via bone or the blood-stream. If the pressure was being relieved, perhaps by a free discharge into the ear or the nose, there might not be high subperiosteal pressure. When there was no such outlet, the high pressure conditions favoured erosion at some other site.

Discussion.

Mr. G. J. JENKINS thought another possible route ought to be considered—namely, between the layers of the diploetic squama in the presence of osteitis.

Mr. T. B. LAYTON said the cases exemplified the fact that it was difficult, under many conditions, to know when bone was inflamed and diseased simply by naked-eye inspection, and the difficulty was increased in the case of denser bone. He asked what was the character of the bone in the cases narrated.

Sir JAMES DUNDAS-GRANT alluded to two classes of cases. One was that in which extra-dural abscess had eroded through the bone, and its presence was indicated by oedema and bagginess at a much higher level than in simple erosion from the mastoid antrum. The second class, described by Grüber, was that in which there seemed to be no connexion with the mastoid cells, and the pointing of the abscess was at a higher level. He had seen such cases clear up following the making of a counter-opening in the roof of the meatus.

Dr. DAN MCKENZIE suggested that some of the cases of the kind were instances of osteomyelitis in which the infection travelled up and produced extra-dural and subperiosteal abscess simultaneously.

Mr. SYDNEY SCOTT spoke of two fatal hospital cases. In one, a man had had middle-ear disease, and during his convalescence from that, multiple abscesses appeared on both sides of the scalp. These were beneath the periosteum and contained a streptothrix. They were very chronic. The mastoid and ear conditions ran a fairly normal course, but the patient eventually succumbed to the abscesses, one in the frontal region leading to a localised osteomyelitis. In the second case the patient had had a large molar tooth removed some weeks before the speaker saw her. She complained of local pain and headache, and a deep-seated abscess formed in the region of the internal pterygoid, and burst in the meatus. The drum was intact, and there was no evidence of mastoid disease; but there was swelling above the zygoma, and it was thought there might be disease of the cells there. She became seriously ill, developed paralysis of the external rectus, and quickly had complete ophthalmoplegia externa, and there was tenderness in the masseter region extending to the zygoma. He explored above the zygoma and found an abscess in the region of the spheno-maxillary fossa. She suddenly developed hemiplegia and became unconscious, and Mr. Scott therefore immediately opened the temporal bone and found a large abscess in the temporal lobe. It had not made itself obvious, but had probably been present through the illness. There had been no middle-ear disease.

Dr. RODGERS, in his reply, said that in all the cases narrated the mastoids consisted of cellular bone. The intervening bone appeared to be healthy.

Otogenic Pterygo-Maxillary Abscess.

Dr. DAN MCKENZIE described the case of a woman, aged 29, to whom he was called to do a mastoid operation, the acute symptoms having come on a fortnight after the left ear had been syringed for the removal of a supposed ceruminous plug. When seen there were great pain and swelling in front of the ear. The swelling prevented the tympanic region being seen. The temperature was 100° F. Pressure in front of the ear led to copious pus being discharged from the meatus. A probe passed into the meatus led through a fistula in the bony floor into a large abscess cavity, and could be passed as far as the submucosa of the pharynx. A radical mastoid operation proved that the original disease was cholesteatoma; and the pterygoid abscess was successfully drained by enlarging the fistula in the meatal floor.

Sequestra of Labyrinth.

Mr. F. W. WATKYN-THOMAS exhibited a girl, aged 18, who, following scarlet fever, developed a swelling over the right mastoid and temporal region, and complete right facial palsy, with deafness on that side. A radical mastoid operation showed cholesteatoma, and a sinus deep to the lateral sinus led to sequestra, which were removed. The facial palsy was slowly recovering.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on March 4th, Sir DAVID WALLACE, the President, being in the chair, when a communication was read by Dr. R. A. FLEMING and Dr. JAMES DAVIDSON on a

Case of Neurocytoma.

It was stated that lately the interpretation of tumours of the nervous system had undergone many changes, and that the present case would previously have been termed a small round-celled sarcoma. It was now recognised that neoplasms of the nervous system might be composed of developing cells of the various parts of that system. Tumours might be formed of the neuroglia, of ganglion cells with nerve fibres, or of comparatively undifferentiated antecedent cells. Tumours were found composed of the forerunners of the sympathetic and chromaffin systems, of the ganglion and neuroglial cells. In 1907 Hutchison recorded ten clinical cases varying in age from 9 months to 9 years, describing a "clinical syndrome" met with in children, which he termed sarcoma of the suprarenal capsule with metastases in the bones of the skull. The onset was usually ascribed to an injury, and the first thing noticed was swelling about the bones of the skull. Other symptoms were ecchymosis of the eyelids, profound secondary anaemia, and signs of increased intracranial pressure, such as torpor and optic neuritis, together with marked proptosis. These cases proved fatal in from 1 to 6 months. The histological appearances in these cases corresponded to the neuroblastomata, but were then classified as sarcomata. Kretz in 1902 suggested that the cells of the suprarenal neoplasm might be of sympathetic origin. This was confirmed by Kuster, who called them "malignant gliomata," while Wiesel in the same year noted the structural similarity in these tumours to the developing sympathetic and suprarenal medulla of the foetus. The varied positions of these tumours could be explained by the fact that the primitive nerve cells wandered out everywhere to form the sympathetic nervous system.

The case in question was that of a boy aged 4, who gave a history of a fall from bed two months previously with no apparent immediate ill-effects. A day or two later slight deafness and swollen veins of the forehead were noticed, and after a week undue paleness caused the mother to seek medical advice. Pains in the head developed, with nausea and vomiting, which, with persistent "black eyes," proptosis, and increase in the size of the head, caused further advice to be sought. Blindness subsequently supervened. On admission to hospital he had marked local prominences of the vertex, especially on the right, suggestive of tumour formation. The veins over the vertex were distended, and oedema of the scalp was noted. There were ecchymoses of both eyelids, and the eyeballs were markedly prominent. The boy was quite blind. The cranial sutures were open, and both fontanelles patent. He sat up in bed with his chin resting on his chest. The spleen was slightly enlarged and there was slight enlargement of the lymphatic glands. The blood showed progressive severe anaemia with leucopenia, and high colour-index with a film similar to pernicious anaemia. His intelligence was good, and his nervous system unaffected, there being no paralysis. X rays showed a woolliness of the frontal and occipital bones. After seven weeks in hospital his temperature rose, he had pains throughout the body, his head increased in size, and he died one and a half months after admission. On post-mortem examination the whole of the subcutaneous tissue of the scalp was replaced by tumour growth up to 1.5 cm. in thickness. The surface of the bone was soft and much eroded. The neoplasm had penetrated the bone and filled most

of the extradural cavity, but was nowhere subdural. The growth had extended through the orbit, enucleating the eyeballs. There was no alteration in the substance of the brain. The marrow of the long bones of the upper and lower limbs was almost entirely replaced by growth which had invaded the shaft of the bones. The left suprarenal was replaced by a large dark mass. Specimens of the case were shown, together with lantern slides of the histological appearances.

Discussion.

Prof. E. BRAMWELL had not met with a similar case. He quoted a case seen recently where tumour formation in a woman of 38 had caused separation of the bones of the skull. It could be felt distinctly, and was confirmed by X rays. Regarding signs of increased intracranial pressure, he had seen a case recently of a glioma without headache, though sight was failing fast, and he mentioned a case in which accident had apparently determined the onset of symptoms of a brain tumour.

Dr. STEWART FOWLER said when this shape of cranium was seen the diagnosis rested between suprarenal tumour and sarcoma. In the former the blood picture greatly assisted the diagnosis. He had seen five cases with enlargement of the head, two of which he had correctly diagnosed. In one case of chloroma the symptoms commenced after a fall.

Dr. JOHN EASON commented on the course of the condition not being as rapid as might have been expected. He had seen the case in life and suspected that it might be a suprarenal tumour.

Dr. FLEMING, in reply, said in his case the injury, a fall, was a severe one; he thought that this had stimulated the condition. He did not think the condition in life to be one of chloroma.

The So-called Parkinsonian Syndrome and Epidemic Encephalitis.

Prof. BRAMWELL then read a paper on the So-called Parkinsonian Syndrome with especial reference to Epidemic Encephalitis. It was pointed out that the number of cases of epidemic encephalitis notified to the Ministry of Health had risen from 541 in 1919 to 1025 in 1923 and 4605 in 1924, an increase not to be explained by the facts that the disease was more generally recognised and that some of the reported cases were probably instances of remission. Among the sequelae of epidemic encephalitis the Parkinsonian syndrome, which derived its name from its resemblance to paralysis agitans, was the most frequent and characteristic. Parkinson in 1817 defined the shaking palsy or paralysis agitans as follows: "Involuntary tremulous motion with lessened muscular power in parts not in action and even when supported, with a propensity to bend the trunk forward and to pass from a walking to a running pace; the senses and intellect being uninjured." But paralysis agitans might be recognised in the absence of tremor; Erb, for instance, among 183 cases met with 37 instances of *paralysis agitans sine agitatione*. Charcot found fault with the term paralysis agitans since weakness was a noticeable feature of the later stages only, while tremor might be inconspicuous or absent; and a relevant objection might be taken to the application of the term Parkinsonian syndrome to this post-encephalitic symptom-complex, since in these cases the rhythmic tremor was seldom observed, while, in addition, Parkinson made no mention of the immobile face and scarcely referred to the peculiar rigidity which characterises the syndrome.

The evidence bearing on the nature and mode of production of the Parkinsonian syndrome was discussed, and Prof. Bramwell remarked that had he known of the brilliant work of the late Prof. Irvine Hunter he would have hesitated to bring this communication before the Society, for Hunter in his

lectures, the first of which appeared after the title of this paper had been intimated, had not only marshalled in great detail the available information bearing on muscle tone, but had also succeeded here in replacing much interesting speculation by proved fact. The effect on muscle tone which resulted from lesions of the motor nerves, of the posterior roots, of the cortico-spinal nerves, and of the cerebellum were referred to. Decerebrate rigidity was briefly considered, and Sir Charles Sherrington's conclusions as to the existence of two features of muscle tone, firstly "contractile" tone, which determines the position of extension of the limbs and reflex standing, and, secondly, "plastic" tone, whereby if the contractile tone were overcome the limb tended to remain in the position in which it was placed. Similar phenomena had been described in man by Kinnier Wilson and others. It had long been known that in certain animals there were two kinds of muscles—viz., the red muscles, the fibres of which, smaller in size and richer in sarcoplasm, exhibited on stimulation a slow and prolonged contraction, and the pale muscles which contracted energetically. Gruetzner in 1887 suggested that the function of some muscles was that of active contraction, that of others intrinsic support. In man the two kinds of fibres were probably intermixed in different muscles in varying proportion. Again, it had been demonstrated by Boeke that the non-medullated nerve-fibres, which Tahiriev had previously shown as proceeding to the thin (red) muscle-fibres, were really sympathetic nerve-fibres, while Kulchitsky's histological observations upon the nerve-endings, published in January of last year, had demonstrated that the medullated (somatic) and non-medullated (sympathetic) nerve-fibres never terminated in the same muscle-fibre. Hunter confirmed Kulchitsky's conclusions from a study of the nerve-endings in skeletal muscles, the sympathetic and somatic nerve-supply to which had been separately divided, while further he showed the effect on muscle tone which resulted in decerebrate animals after division of the somatic and sympathetic nerve-supplies. Hunter concluded from his observations on animals and man that the function of the sympathetic nerve-supply of skeletal muscle was the maintenance of posture once the position was attained, or, in other words, that it was responsible for the property of plastic tone described by Sherrington. Further, he demonstrated that plastic or sympathetic tone was subserved by reflex arcs, the afferent limbs of which passed upwards in the lateral column to the brain stem, while further he suggested that the efferent limbs were constituted by the ponto-spinal tracts described by Buzzard and Collier. The peculiar rigidity met with in the Parkinsonian syndrome Prof. Bramwell held would appear to be an exaggerated plastic tone, of the nature of a release phenomenon, due to cutting off of cerebral impulses, as was the increase of contractile tone or spasticity which resulted from interruption of the cortico-spinal neurons, the responsible lesion being situated in the corpus striatum. It was further of interest to note that the experimental observations of Warner and Olmsted indicated that the frontal lobes inhibited decerebrate rigidity. Schuster had reported a case of frontal tumour presenting symptoms resembling paralysis agitans. From an anatomical study of this case and others reported in the literature Prof. Bramwell was of opinion that the symptoms in question are probably to be explained by pressure or other involvement of the basal ganglia, and that there was no anatomical evidence to prove that they were directly attributable to involvement of the fronto-pontine tracts.

Discussion.

Prof. W. RUSSELL remarked on the connexion between the voluntary and involuntary supply to muscle, a point of great interest, which had been worked upon to a great extent by Gaspard and lately by I. Hunter. He commented on the extent to which

nerve paths had been mapped out of late years, and suggested that there might be in these conditions some interference with the psychic control in addition. Concluding, he said that these discoveries helped in the understanding of the conditions but not in therapeutics.

Dr. EASON said considerable difference existed in ideas regarding the sympathetic system. On the one hand it was taught that stimulation of this system by a flow of adrenalin caused increased action, on the other it was said that increased plastic tone was produced with immobility.

Dr. BRYCE said this sympathetic immobility might be the factor which caused a frightened hare to crouch.

Dr. FLEMING commented on the difference in mentality in the two conditions, paralysis agitans and epidemic encephalitis. In the former the mentality was alert, in the latter dull. He also referred to Hunt's work on juvenile cases of paralysis agitans.

Prof. BRAMWELL, in replying, claimed no originality for his communication. He agreed that the difference in mentality in the two conditions was great, and helped greatly in diagnosing between the conditions. Hunt's work he did not think had been corroborated. He thought the psychic point of view important, and recent work had been rather along physiological lines. He hoped that as a result of investigation some means of treatment might be arrived at.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

A MEETING of this Section was held in the Royal College of Physicians of Ireland on March 6th, Dr. F. C. PURSER, the President, in the chair.

Dr. L. ABRAHAMSON read a paper on two cases of

Congenital Dextrocardia.

The first was a case of complete transposition, with sino-auricular block. The patient, aged 43, female, consulted a doctor because of pain referred to the right præcordium and of palpitation. Her previous illnesses included two attacks of pleurisy and several attacks of gastric trouble. When 9 years of age she complained of pain in the right præcordium and was found on examination to have dextrocardia. She had had several similar attacks, and on one occasion developed a convulsion and became unconscious. On examination the pulse varied in rate from 42 to 60 beats per minute. There were frequent pauses occurring at irregular intervals. The apex beat was found in the fifth right interspace. Cardiac dullness was elicited on the right side, liver dullness on the left side, and gastric tympany on the right side. X ray examination showed complete transposition. Electrocardiograms, demonstrated by lantern slides, showed inversion of waves in lead I, and frequent pauses due to the presence of sino-auricular block.

The second case was one of complete transposition. The patient, a male, aged 43, complained of no symptoms referable to the heart. Previous history and family history were negative. On examination the apex beat was found in the fifth right intercostal space, just inside the nipple line. Cardiac dullness and gastric tympany were elicited over the right side, liver dullness on the left side. X ray showed complete transposition. Electrocardiograms showed inversion of waves in lead I.

In reply to Dr. T. G. MOORHEAD, Dr. ABRAHAMSON said that he had seen one case of isolated dextrocardia, and four cases of transposition of the heart and transposition of the viscera.

Dr. ABRAHAMSON also made some observations on a case of

Auricular Fibrillation with Slow Ventricular Rate.

The patient, aged 61, male, had suffered for many years from cough with expectoration. For three years prior to admission to Mercer's Hospital the cough had become associated with increasing breathlessness. On examination the patient showed orthopnoea with some cyanosis. The pulse was regular, rate 50 beats per minute. Blood pressure: 190 systolic, 85 diastolic. There was evidence of emphysema and of chronic bronchitis. The heart did not show any apparent enlargement; a systolic murmur was audible over the mitral area and was not conducted. There was some tenderness over the liver. A course of squills and digitalis had been administered before the patient came under observation. An electrocardiogram taken on Feb. 14th showed the presence of auricular fibrillation with complete regularity, rate 50 approx. Digitalis was discontinued. A tracing taken a week later showed auricular fibrillation with slow but irregular rhythm. Quinidine treatment was commenced. After a total dosage of 345 gr., fibrillation disappeared and an electrocardiogram showed return of the "P" wave, whilst there was a clear picture of incomplete heart-block with periodic dropped beats. Subsequent tracings all showed incomplete heart-block. Illustrative tracings were demonstrated by lantern slides. The case was accordingly reconstructed as follows: (1) Myocardial disease with incomplete heart-block; (2) supervention of auricular fibrillation, rate slow owing to the incomplete heart-block; (3) heart-block becoming complete, probably as a result of administration of squills and digitalis. As a result the rhythm was slow and quite regular. The case showed clearly that the slow rate during the stage of fibrillation was due to heart-block. Injection of atropine did not quicken the heart-rate.

Dr. W. M. CROFTON said it was a remarkable thing that these cases of heart-block could become unblocked. He had recently seen a case somewhat similar to the one described by Dr. Abrahamson, but the patient had rheumatism as well as the heart trouble. The patient was treated by the usual methods and improved, although irregularity was still present. He had found *B. coli* in the urine and had made a vaccine, and the patient was having injections of it. He drew attention to the possibility of making the cure in these cases more permanent by the use of vaccines, as very often only temporary improvement was got by giving quinidine.

Dr. MOORHEAD asked if the patient's clinical symptoms disappeared when the fibrillation disappeared.

Dr. ABRAHAMSON replied that cases of rheumatic heart-block generally recovered, and he thought that Dr. Crofton's case would have become free from heart-block without the use of vaccine, as in these cases the heart-block disappeared of itself. The patient's clinical symptoms had not improved from the use of quinidine, but he had not really expected that they would. He had employed the drug more from an experimental point of view. He thought the patient would always have incomplete heart-block, but this of itself would not be harmful. He had seen one case in which there had been evidence of cerebral embolus resulting from the use of quinidine, but this case had made a complete recovery. He had also seen one case in which the patient had died after receiving 3 gr. of quinidine, but he did not think that the quinidine had had anything to do with the result in this case, as the patient was of the type in which sudden death was not uncommon. The interesting point in his (Dr. Abrahamson's) case was not that the digitalis had produced heart-block, but that it had produced complete heart-block with regular rhythm. This could not have been diagnosed as a case of auricular fibrillation had it not been for the electrocardiograms.

Dr. CROFTON read a paper on Encephalitis Lethargica.

Reviews and Notices of Books.

THE CHEMICAL ASPECTS OF IMMUNITY.

By H. GIDEON WELLS, Ph.D., M.D., Professor of Pathology, University of Chicago; Director of the Otho S. A. Sprague Memorial Institute. American Chemical Society Monograph Series. New York: The Chemical Catalogue Co., Inc. 1925. Pp. 254.

THE object of these monographs is to show the relation of chemical science to other branches of work, and to demonstrate the fact, sometimes not appreciated even by chemists, that "their investigations may be connected with other work which on the surface appears far afield from their own." When one reads the list of monographs already published, and of those in the course of preparation, it is clear that the American Chemical Society have set themselves a heavy task, and provided that the monographs in themselves are of a high standard, the benefit conferred upon readers will be great.

The present volume deals with the chemical basis of immunity. The style is condensed and a great deal of information has been included in the 254 pages. In places the book resembles a catalogue of scientific facts and observations, and thus it cannot be said to form attractive reading. Prof. Wells obviously found himself faced with the alternatives of a general account in an easy style, or of a more or less complete summary of the work done in this field. He chose the latter course. Looked at from the standpoint of the experienced worker in pathology, there can be no doubt but that the monograph in its present form is the more valuable. After a general introduction and a definition of terms, the author deals with the chemical nature of antigens. The whole question is treated very fully; it is astonishing to find no reference here to the Wassermann antigen, which is discussed under another heading. The next chapter deals with immunological specificity. The author here emphasises the fact that immunity reactions, such as precipitin formation and anaphylaxis, are capable of demonstrating differences between proteins which are indistinguishable by chemical means. The modification of specificity by the introduction of various radicles into the protein is also dealt with. The chapter upon the chemical nature of antibodies is, of necessity, unsatisfactory, since nothing is definitely known concerning these bodies. The chapter consists mainly of a list of the physical properties and immunological reactions of sera containing them. The section dealing with the various theories upon the neutralisation of toxins by antitoxins is very complete; the recapitulation is judicial. Arrhenius' and Madsen's, and Bordet's views are admirably and fully set out. The theory of Ehrlich is hardly given a fair description, and it would appear that Prof. Wells either intends to ignore these views or assumes that his readers are fully conversant with them. The next chapter deals with agglutination and precipitation reactions. These have received much attention elsewhere, consequently the chapter has less general interest than some of the others. The next two chapters, dealing with "lytic reactions" and the Wassermann reaction, are the most disappointing. The general description of hæmolytic systems is almost elementary. The section upon the Abderhalden reaction is non-committal. Surely we have a right to expect an authoritative statement from a writer of such wide experience on a reaction that continues to be perpetuated in all books, though few experienced workers will sponsor its claims. It is also surprising that no mention is made of the recent work in Germany of Paul Hirsch, who employs an interfereometer to interpret the reaction. The Wassermann reaction is dealt with in an almost superficial manner. The work of J. McIntosh is only very briefly referred to, and that of Heizfeld and

Klinger and of many other observers completely ignored.

The last chapter deals with anaphylaxis and allied phenomena. Each chapter is followed by an excellent recapitulation and a series of references. The amount of work put into the book must have been enormous, and Prof. Wells has undoubtedly done a great service to those seeking information in this field. But the present volume seems to lack that personal touch which is so characteristic of the author's splendid works on "Chemical Pathology" and "Chemistry of Tuberculosis."

AN X RAY ATLAS.

An X Ray Atlas of the Normal and Abnormal Structures of the Body. By ARCHIBALD MCKENDRICK, F.R.C.S.E., D.P.H., F.R.S.E., Surgeon-in-Charge of the Surgical X Ray Department, Royal Infirmary, Edinburgh; and CHARLES R. WHITTAKER, F.R.C.S.E., F.R.S.E., Assistant Lecturer in Anatomy, Surgeons' Hall, Edinburgh. Edinburgh: E. and S. Livingstone. 1925. Pp. 222. 25s.

IN the first paragraph of the preface of this work it is stated: "In this atlas an attempt has been made to provide a series of radiograms illustrating the normal and abnormal structures of the body, and also the more common injuries and diseases. To lend interest to the work a few rare conditions have been added." This is an ambitious programme, and if the authors have not quite succeeded in the formidable task they have set themselves, they have at least collected together an admirable and representative collection of radiograms. It would have been an improvement from the student's point of view if a little more trouble had been taken to make clear which are the rare conditions pictured. The book is divided into four main sections—normal joints and limbs; injuries and diseases of the limbs; head, neck, thorax, and spine; abdomen. In each section radiograms are reproduced with either very brief descriptions or diagrams of the normal, or both. The pictures which illustrate the chest section, which is a region of great importance in this connexion, are too few in number. Doubtless the authors have verified their diagnoses, and have information at disposal that the reader cannot have, but the reproduction on p. 128 of a film of a case of achondroplasia looks very like that of a case of rickets, while the case of cyst of the humerus (p. 136) appears to be complicated by the presence of an exostosis. In a subsequent edition the authors could, with advantage, be somewhat more precise in the description of normal conditions if the work is to be of real value to the student.

The atlas, as a whole, is excellently produced and should make a wide appeal.

PHYSIO-THERAPY IN GENERAL PRACTICE.

By E. BELLIS CLAYTON, M.B., B.Ch. Cantab., Director of the Physio-Therapeutic Department, and in Charge of the Massage and Electrical School, King's College Hospital. London: Baillière, Tindall and Cox. 1924. Pp. 174. 18s. 6d.

THE author states in his preface that this book "has been written for the medical practitioner and the masseuse." It includes, he says, "descriptions of treatments . . . which a masseuse . . . should be able to give though she may have learnt slightly different methods. The treatments described . . . are based on the methods used at King's College Hospital." Practitioners who have no extensive physiotherapy experience will find the explanatory chapter which begins the book of great value. A section is devoted to crawling exercises, a study which

Dr. Clayton has made essentially his own. An excellent series of photographs illustrate the text. The book, as a whole, is an epitome of physical treatment. The masseuse will find an indication of the broad lines she should follow, and the physician a fair idea of what he might prescribe. But there is a certain lack of precision in some of the statements. For example, anyone reading p. 96 might conclude that the iliac colon is frequently distended with faeces, while pp. 94 and 97 read together do not give a convincing account of the rationale of the treatment advised. The author expresses doubt whether electrical stimulation through the abdominal wall ever produces direct contraction of the muscles of the stomach or intestines, while three pages later he advises the application of faradic stimulation along the course of the colon for the relief of constipation. He advises that a case of empyema should be treated with breathing exercises as early as possible after the operation. He treats dislocation of the shoulder-joint by bandaging the arm to the side for two or three days, abduction being prohibited for a week after the accident. No guide is given as to the choice of splintage after injury. That the author has conservative views with regard to the use of physical treatment after fracture may perhaps be gathered from his advice that massage and movement will probably have to be delayed till at least three weeks after fracture of the surgical neck of the humerus.

This little book should be pleasantly read, for the wide range of physical treatment at his disposal is not sufficiently appreciated by the practitioner.

THE CHILD AND HIS PROBLEMS.

By ALICE M. HUTCHISON, M.D., M.R.C.P. London: Williams and Norgate. 1925. Pp. 168. 5s.

THIS book, which is introduced to the reader by Dr. Crichton Miller, is intended for parents and teachers. The factors which influence the development of the child are discussed in simple and homely language which should be comprehensible to a wide circle of readers. The author's standpoint is decidedly that of the environmentalist, and those who regard heredity as the major factor will not always agree with her views as to causation. Some, for instance, may regard the statement that "the difficult child is the product of his environment" as a half-truth of doubtful value, and that "he is absolutely certain to be transformed again into a normal child once he finds himself in the right atmosphere" as likely to cause some disappointments. Such criticisms as these, however, do not touch the main scope of the book, which is not theoretical instruction, but practical advice; the latter is sound and reasonable throughout, and its acceptance by parents should obviate a large measure of domestic discord.

SMOKE RINGS AND ROUNDELAYS.

Blendings in Prose and Verse since Raleigh's Time. Compiled by WILFRED PARTINGTON. Woodcuts by NORMAN JANES. London: John Castle. 1925. Pp. 320. 7s.

THIS compilation is dedicated to "A Thousand and One Nights spent over Pipe, Cheroot, and Cigarette with Many Good Friends, East and West," and comprises a large number of passages, many of them drawn from well-known literature, and all having the common design to exalt the humanising influences of tobacco. The excerpts are of varying literary merit, but their range will surprise many readers, for, while there are some poems and prose passages universally familiar, there are others which few will have remembered and many that will be new to most. The symposium introduces us to many new advocates of nicotine, whose praise is introduced

from many novel points of view. It is good to have brought together under the title of "A Pipe of Tobacco" the six imitations due to Isaac Hawkins Browne; they are often referred to and seldom seen in print. Both Mrs. Piozzi and Boswell testified to Johnson's admiration of this author, but it would seem from what is known of him that he could not smoke without drinking, and that in that connexion he smoked too much. A favourite passage from Thomas Carlyle's "Frederick the Great" is quoted wherein the sage points out that tobacco smoke is "the one element in which by European manners men can sit silent together without embarrassment, and where no man is bound to speak one word more than he has actually and veritably got to say"; this use of tobacco is very well known at committee meetings, where the man who is smoking is neither supposed to speak if he does not want to, nor expected to answer questions on the spot, as he has to attend to whatever he is smoking. He thus obtains time to make up his mind.

An amusing little book.

JOURNALS.

QUARTERLY JOURNAL OF MEDICINE.—The January number contains the following articles: Some Factors of Significance in Adolescent Goitre, by H. Gardiner-Hill, P. C. Brett, and J. Forest-Smith. A series of 100 cases of goitre occurring in patients between the ages of 10 and 20 years were the subject of this investigation. Of these, 79 per cent. were of a colloid type, 16 per cent. exophthalmic goitres, 3 per cent. adenomata, and 2 per cent. endemic goitres. The investigations included clinical observations, physical measurements, basal metabolism, and sugar-tolerance estimations. Thyroid function was found to be apparently normal in 42 per cent. of colloid goitres, but in 32 per cent. there was evidence of hyperthyroidism, and in 26 per cent. of hypothyroidism. The blood-sugar curves were delayed in both hyper- and hypo-thyroidism, and the blood-sugar content was raised in hyperthyroidism.—A Case of Virilism Associated with Suprarenal Tumour: Recovery after its Removal, by Gordon Holmes. The patient, whose case is here recorded, had a tumour arising from the cortex of the right suprarenal. It was found to be innocent, and nine years after its removal there was neither local recurrence nor metastases. The operation was performed when the patient was 26 years old. Her health had been normal until the age of 17, when menstruation ceased, and when 19 years old hair began to grow on the chin and upper lip. This was followed by a growth of hair on the legs, loss of feminine contour, and alteration in her mental state. Removal of the tumour was followed 36 days later by reappearance of menstruation, which had been absent for nine years, and by the return of her feminine physical and mental characteristics. A plate is included showing the microscopical appearance of the tumour, and for comparison those of a somewhat similar tumour which is preserved in the museum of the Royal College of Surgeons of England—a case recorded by Knowsley Thornton in 1890.—Epidemic Encephalitis: the Second Winnipeg Outbreak, by William Boyd. There have been two outbreaks of epidemic encephalitis in Winnipeg, one in 1919–20, and the other in 1922–23. Clinically, the former was of a somnolent and the latter of an excited type. A detailed description is given of the main features of the disease, and the special points of its pathology are considered. Acute calcification of the small arterioles of the basal ganglia was noted in young subjects, the larger arteries at the base of the brain being free from atheroma and calcification. The microscopical appearances of the calcareous deposits are shown in the two plates.—The Sugar Content of Blood in Normal and Under-nourished Children, and the Effect of Fat on the Absorption of Carbohydrate, by Muriel J. Brown. The blood-sugar content was studied in normal and

under-nourished children. Using MacLean's method the normal blood-sugar in infants up to the age of 2 weeks varied between 0.072 and 0.097 per cent., and between the ages of 6 weeks and 1 year from 0.086 and 0.116 per cent. In conditions of under-nutrition the blood-sugar lay between 0.072 and 0.116 per cent. Whereas vomiting causes a fall in the blood-sugar level, it is unaffected by diarrhoea. Sugar-tolerance curves were also worked out and similar results were obtained in the normal and under-nourished child.—Progressive Lipodystrophy, by W. N. Boog Watson and W. T. Ritchie. Three cases of this rare condition are here described. No light can as yet be thrown upon its pathology. The characteristic features are well shown in the plates. The journal concludes with an account of the proceedings of the Association of Physicians of Great Britain and Ireland, whose eighteenth general meeting was held at Bristol in June, 1924.

The Geographical Distribution of Exophthalmic Goitre in the British Isles, by J. M. H. Campbell. In this paper the author has amplified his work (*Quarterly Journal of Medicine*, 1921–22, xv., 64) on the distribution of exophthalmic goitre in England and Wales by including the figures for Scotland and Ireland as shown by the death returns in the Registrar-General's annual reports. The distribution of deaths from exophthalmic goitre in Great Britain and Ireland is indicated in two maps. One is divided into 11 areas, each with a population of 2,000,000 or over, and in the other the county boundaries are shown. It is seen that Graves's disease is especially prone to occur in the West of England and in the central part of Wales. The town incidence of Graves's disease is also discussed. With regard to endemic goitre there is very little accurate knowledge of its distribution in England, although certain parts are associated with it. On the evidence at hand it appears that in the British Isles exophthalmic goitre is more liable to occur in districts where simple goitre is endemic. On comparing the death-rate from Graves's disease with the birth-rate in different towns it was found that a low birth-rate is associated with a high death-rate from exophthalmic goitre, and vice versa.

New Inventions.

AN IMPROVED RUGINE OR RASPATORY.

THE rugines illustrated are a modification of Ollier's original pattern. The handles give a more comfortable grip than those of the original model. The shaft has been specially lengthened and the finger rests placed

FIG. 1.

near the handles so as to obviate the risk of accidentally introducing the fingers into the wound in plating and bone-grafting operations. The edge of the rugine is of razor-like sharpness. These rugines were copied from a pair devised by Major H. Pierpoint, I.M.S.,

FIG. 2.

and made under his direction at the War Hospital, Ambala, in the hospital workshop by Indian labour from materials available in the bazaar. I have found them invaluable in bone-grafting and bone-plating operations.

Messrs. Down Bros., St. Thomas's-street, S.E. 1, are the makers. H. HALLILAY, Lieut.-Colonel, I.M.S.

THE LANCET.

LONDON: SATURDAY, MARCH 21, 1925.

MEDICAL PARTNERSHIPS.

IN an action tried recently in the Chancery Division a medical man sought dissolution of partnership from a medical colleague upon grounds which, if they had been established, would no doubt have entitled him to succeed. The plaintiff's evidence, however, failed to make out his case to the satisfaction of the judge and the action was dismissed with costs, his Lordship saying that all the charges, and some of them were grave, preferred by the one partner against the other had been disproved. It was apparent to those of our readers who gathered the details of the case from the daily press that the ventilation of the dispute in public was prejudicial to the interests of both parties to it, and no doubt this consideration prevents similar actions from being tried, but no other course may be open to those who find themselves unfortunately linked together in the conduct of a medical practice. Some sort of an arbitration clause may be attempted, but, as occurred in the case referred to, it may not provide for the reference to an arbitrator of the points that are at issue. The dissatisfied party is then obliged to have recourse to Section 35 of the Partnership Act, 1890, which enables a partner in any kind of business to apply to a court of law for dissolution in various cases which include conduct such as "in the opinion of the court, regard being had to the nature of the business, is calculated to prejudicially affect the carrying on of the business, or when in matters relating to the partnership business a partner's conduct is such that it is not reasonably practicable for the other partner or partners to carry on the business in partnership with him." In the ordinary agreement between medical partners, a form of which will be found in "Barnard and Stocker's Medical Partnerships," arbitration upon any dispute touching the partnership is included, and we do not know whether this published form was used or not in defining the relations in this particular case. But, anyhow, the plaintiff's counsel found the arbitration clauses, if any, in the deed of partnership not to be full enough to render arbitration obligatory in lieu of the trial in open court which took place.

No one who is acquainted with the business side of professional life, and who knows the difficulties which surround the conduct of, and the arrangements for, medical partnerships, will be surprised that the deed of partnership was found ineffective. These difficulties may arise in ways that can hardly be contemplated in any uniform manner by those who draw up deeds of partnership, so that troubles occur which are not familiar to lawyers, and only vaguely guessed at by medical men, while it would seem that medical agencies have also much to learn in this direction. Therefore, regrettable though such legal actions as that which was recently tried are from some points of view, the publicity serves a good purpose in making all concerned careful about the terms of partnership to which they are asked to subscribe. There are situations, easily to be thought of, whose risks can, none the less, only be provided against with great skill in draftsmanship, while the mention of

these risks might be considered as insulting and prejudice mutual good feeling at the outset. Perhaps such things as we have in mind may not happen often, but when they do they constitute a tragedy, incompatibility of temperament and outlook making of medical partnership a weakness instead of a strength, a farce instead of a contract. It may be granted that, as a rule, two or more fair-minded men can arrange so that the interests of their patients, which is another way of saying the proceeds of their professional work, shall benefit by collaboration and even by the personal contrasts which they may display. But where collaboration is impossible and partnership becomes a misery, the only way out appears to be a dissolution of partnership. Few deeds of partnership answer in a satisfactory way the crucial problem of who shall stay and who shall go, for it may be assumed that separation of interests usually implies separation of locality. Both partners may see that they had better separate, but each will consider that it is the other who should be paid out, while there is usually no arrangement by which the exact sum to be paid can be calculated. Nothing can constrain the partner who is reluctant to go to accept the sum of money that is offered to him, which in such circumstances is generally quite inadequate. And nothing can constrain the man who would pay his partner out to pay the right price, where the deed gives no basis for a detailed arrangement.

It would seem, therefore, desirable in deeds of medical partnership to have a full and explicit clause which would provide that all disputes, including those which arise out of quarrels or out of the alleged conduct of a partner, should be referred to an arbitrator. It might be desirable to state in the clause expressly that such an arbitrator should have power to dissolve the partnership, and to define the kind of arbitrator to be appointed as well as the manner of his appointment. In medical partnerships questions of the proportional return of premiums, of practice in the same neighbourhood, as well as questions of medical ethics and appropriate conduct, point naturally to the necessity for an arbitrator well acquainted with all the conditions of medical practice. The Court in the recent case, to quote the judge's words, "heard with some surprise that a life-long partnership was by no means unknown in the profession," but it is not an uncommon expression in partnership deeds.

SCIENTIFIC COPYRIGHT.

IN the history of scientific investigation there are not a few instances in which a research worker has seen others grow rich by the industrial exploitation of some discovery which he has made but from which he has been unable to derive financial profit. Should there not be copyright in scientific as in literary or artistic work? Nearly 50 years ago the law courts decided that the mere discovery of a natural law was not patentable; the chemical truth that pure sulphides will absorb the sulphur compounds was held not to be a proper subject-matter for letters patent; and we have hardly made much progress beyond that position to-day. Yet there is some encouragement in the recent report of the British delegates upon the general work of the Fifth Assembly of the League of Nations. The Committee of Intellectual Coöperation, it appears, has been requested to consult with the Economic Committee and to organise this year a conference of experts to consider recent proposals on the question of scientific property. The proposals referred to are those of

Senator RUFFINI, who has reported to the Committee of Intellectual Coöperation in terms discussed in an interesting article contributed by an American legal writer, Mr. E. S. ROGERS, to the recent issue of our learned contemporary the *Journal of Comparative Legislation*. Senator RUFFINI has been pointing out the injustice of our present system which recognises the two extremes of intellectual work, the base and the summit. The man who invents a new india-rubber heel can patent his invention and make his fortune. At the opposite end of the scale the musical composer who can give to the world a Ninth Symphony can secure the pecuniary profits which are his due. Between the two extremes is the worker in the field of scientific research who observes a truth from which mankind will derive immense and everlasting advantage: to him the law gives nothing. The Senator remarks that such a worker might be recompensed in either of two ways. He might be given the right to exploit his own discovery, but, since the gifts which bring success in the laboratory are seldom accompanied by those which bring fortune in the market-place, this privilege might be illusory. Alternatively he might be given the right to a sort of royalty on profits made by the industrial application of his discovery within a specified period, the suggested period being the discoverer's life-time and 50 years thereafter. As Senator RUFFINI suggests, the objections to recognising any legal right of the research worker in the creations of his mind may be expected to be exactly the same objections as were formerly raised against the claims of the artist and the inventor. Mr. ROGERS pleasantly develops the suggestion. He narrates the long campaign against literary copyright from the time of JOHN MILTON to the time of SAMUEL JOHNSON. He bids us prepare for just the same outcry against monopoly and the same enthusiasm for the interests of the people as DICKENS satirised in the speeches of Mr. GREGBURY, M.P., to NICHOLAS NICKLEBY. "The creations of the pocket," said that great statesman, "being man's, might belong to one man or one family; but the creations of the brain belong to the people at large." Those who write for posterity should be content to be rewarded by the approbation of posterity; "anything put strongly about the people comes out very well at election times"; nobody need consider the feelings of the authors—"I believe the greater part of them live in lodgings and are not voters."

If history is going to provide a parallel between literary and scientific copyright, then the period of hostility will end in the ultimate recognition of the justice of the claim. The administrative difficulties of protecting scientific discovery will doubtless be formidable, but the task of protecting industrial inventions by the issue of letters patent must have seemed at one time equally impracticable and yet has not been found impossible. It would be rash to prophesy in what form the change of law will come. It may come in the form of a Convention on Scientific Property approved by the League of Nations after patient search for an acceptable formula. The English statute book has shown in the last few years that many legislative projects approved at Geneva are being incorporated in our law, especially, for example, in relation to regulating the conditions of labour. Or the change may come more gradually by the slow enlargement of the scope of patentable processes and methods. Signs of a movement in this direction are occasionally visible in Germany and elsewhere when the results of bacteriological work begin to be patented. By whatsoever means the change may come, it is hard to believe that in ten years' time

the law will not ensure some measure of protection and recompense to scientific research such as it now gives both to artistic and literary work and to industrial inventiveness.

STUDIES IN COMPENSATORY HYPERTROPHY.

THE determination of what degree of functional derangement may be expected to follow definite organic lesions is difficult. There appears to be only a loose correlation between the bulk of an organ and the work it can perform. It is known, for example, that an animal can live in perfect health with only a quarter of the normal amount of renal tissue. Yet we have the curious anomaly that if one kidney is destroyed by disease the other tends to undergo a very considerable hypertrophy. V. R. KHANOLKAR'S¹ work suggests that only limited areas of each kidney function simultaneously, and that the functioning areas shift continuously so that no part of the organ is overworked. In response to extra demands other areas become active, and in this way the kidney is capable of a wide range of activity. This probably explains the necessity for compensatory renal hypertrophy. But the principle cannot be of universal application, for as A. E. BOYCOTT and C. H. KELLAWAY have shown,² removal of one suprarenal gland is not followed by hypertrophy of the other.

PEYTON ROUS and PHILIP MCMASTER have published³ some interesting observations bearing on the question of compensatory hypertrophy of the liver. It has been shown that three-quarters of the liver can be removed without causing more than temporary circulatory derangements, but rapid regeneration of the remaining quarter takes place till the original bulk of the organ is restored. If instead of ablation the circulation is diverted from part of the organ, the anæmic part atrophies and the remainder hypertrophies; and the changes take place concurrently so that at any particular time the total bulk of the liver is approximately that of the entire normal organ. Further, if compensatory hypertrophy is prevented in the unaltered moiety, atrophy fails to occur to any degree in the anæmic portion. It has been suggested that these curious phenomena are brought about in response to some functional demand of the body, and the question immediately arises, Which particular function of the liver is particularly essential to the body? Is it one or is it all of the normal activities of the organ which are so necessary?

In order to settle this question ROUS and MCMASTER repeated the experiments, using fasting animals so as to eliminate any functional stimuli due to the assimilation of food from the alimentary tract. Rats were the animals of choice for various reasons, one of the most important being that liver regeneration in them is extremely rapid, being complete in about two weeks. In rats receiving water but no food the liver diminishes in size to a remarkable degree; of all the other tissues, adipose tissue alone loses more weight. Two explanations for this have been suggested—one, that the liver is actually utilised as food; the other, that the loss in weight is due to a lessened functional demand due to the fasting. If the former explanation is correct, then compensatory hypertrophy after partial ablation of the organ should not

¹ *Journal of Path. and Bact.*, 1922, vol. xxv., No. 4, p. 414.

² *Ibid.*, 1924, vol. xxvii., No. 2, p. 171.

³ *Studies from the Rockefeller Institute for Medical Research*, 1924, vol. i., p. 27.

occur if the animals are starved subsequently to the operation. But if the liver is really functionally necessary to the body, even though fasting, then some recognisable degree of compensatory hypertrophy should occur under the conditions of the experiment. Putting this to the test, ROUS and McMASTER found that hypertrophy did, in fact, occur. They removed by operation more of the liver than persists in the starved but intact animal, and found that the fragment left did actually undergo hypertrophy. In the starving intact animal some of the liver is, no doubt, utilised as food; the fat and glycogen stored up in it are certainly mobilised for the purpose. But the main loss of bulk would seem to be due to the lack of normal functional stimuli from the alimentary canal. That stimuli exist, other than those arising from the digestion of food, is conclusively shown by these experiments. The exact nature of these stimuli is as yet uncertain, but it may be hoped that further work will clear up this important point.

Annotations.

"Ne quid nimis."

THE NEED FOR A NEW FACTORIES BILL.

THE conditions under which workers in factories are employed form one of the most important questions in our national life. Our present legislation with regard to factories is based on the Factories and Workshops Act of 1901, and although many progressive changes have been made under its powers, our industries, and indeed our whole social outlook, have developed and changed to such an extent since the beginning of the century that the need for new legislation has become an important issue. A year ago in these columns we published a series of articles on changing factory conditions, their rising standards and future developments,¹ in which we advocated the introduction of a new and comprehensive Factory Bill at the first good opportunity. Such a Bill was drafted when Mr. Bridgeman was Home Secretary, and received a first reading under the Labour Government. When that party went out of power Mr. Baldwin in his election address pledged himself to give the Bill a second reading, and mention was made of it in the King's speech. So far, however, nothing further has been done, but the new Bill does not lack enthusiastic support. On March 10th a deputation organised by the Industrial Bureau of the Young Women's Christian Association attended on the Home Secretary, Sir William Joynson-Hicks, to urge upon him the introduction and passing of the Bill. The deputation was composed of members of 28 societies, mainly women's organisations, and was representative of many different aspects of industrial and social life. The deputation was introduced by the Bishop of Winchester, the various speakers being Miss Gertrude Tuckwell, vice-chairman of the Bureau, Lady Ware, vice-chairman of the Executive Committee of the Conservative Women's Reform Association, Mrs. C. D. Rackham, late Inspector of Factories, a working woman whose name was withheld, and Miss Knight Bruce of the Industrial Christian Fellowship. The general aim of the measure to which it is sought to give effect is to amend the Act of 1901 and to consolidate with it eight other Acts which have been added to the Statute Book between 1901 and 1924—it simplifies while it combines the mass of existing factory legislation.

Among the features of the new Bill are the provision of a 48-hour week for protected persons as against a 60-hour week under the old Act, improved regulations in regard to safety, temperature, and ventilation, regulations regarding lighting, fire, and

welfare, certification of the fitness of young persons, and weight-lifting by women and young persons. In reply to the deputation, the Home Secretary pointed out that the Government had also to consider the employers', the commercial, and the financial sides to the problem. He pledged himself that a Bill would be introduced into Parliament this summer to deal with factory legislation, but that Bill, he said, would not necessarily be the measure proposed by the last Government. There was no doubt that it would be a consolidation Bill, and it would also bring the position in regard to the safety and efficiency of factories very much farther than did any existing laws. Several debatable points still remained to be decided, particularly in regard to the regulation of adult hours of labour by Act of Parliament, and, he said, the Government would have to consider whether to include in a factories Bill a clause of such far-reaching importance as the regulation of women's hours of labour by legislation. He pointed out that while he did all he could to improve the position of the workers, he had to take care that he did nothing which would cripple our own industries in competition with the industrialists of other countries. The welfare of the workers has at least not been shelved, and we trust that the present Government will spare no pains to promote—to use the the pregnant word of the Home Secretary—the "efficiency" of our factories.

THE INFECTIVE FILTRABLE VIRUSES.

THE difficulties inherent in work upon the infective filtrable viruses is known to all who have touched even upon the edge of the subject. That they are not of the sort which when faced flee away is obvious from the paucity of results attained to the present, in spite of the keen and unremitting work which is proceeding upon the subject in all parts of the world. Careful and painstaking attempts to isolate the virus of varicella are reported by Dr. Thomas M. Rivers and Dr. William S. Tillett from the hospital of the Rockefeller Institute.¹ By intratesticular inoculation of blood from patients suffering from chicken-pox into rabbits these authors were able to isolate a filtrable virus which they passed in series through nearly 70 rabbits. This they called Virus III. Although it never gave rise to any lesions clinically resembling those of varicella, it behaved in a definite and specific manner upon intratesticular, intradermal or intracerebral inoculation. Introduced by the first route it gave rise to pyrexia and malaise; intradermally it produced a characteristic local lesion, while on intracerebral inoculation it gave rise to histological appearances and clinical symptoms resembling those produced by the introduction of the virus of symptomatic herpes, but differing from this latter in never causing death. After inoculation by any of the above routes rabbits developed an immunity as demonstrated by failure on their part to show symptoms on subsequent inoculation. All these results appeared to point to the conclusion that in Virus III. Dr. Rivers and Dr. Tillett had indeed laid their hands upon the virus of varicella. In accordance with the high traditions of the Rockefeller Institute, however, these workers did not allow the matter to rest there. Further researches showed that the blood of patients convalescent from chicken-pox conferred no immunity upon rabbits against the virus. Finally, two healthy volunteers, one of whom had had chicken-pox and the other of whom had not, were inoculated in the arm with the virus. The subject who had never had chicken-pox developed no symptoms, while, on the other hand, the one who had had the disease, and was presumably immune against it, suffered from a severe disorder associated with malaise, fever, and swelling of the arm and regional lymph-glands, which took five days to subside. On the basis of their present data the authors are forced to the conclusion that Virus III. bears no relationship to clinical

¹ THE LANCET, 1924, i., 304, 354, and 411.

¹ Studies from the Rockefeller Institute for Medical Research. Reprints, vol. II., p. 325.

varicella. Where it came from and what, if any, is its bearing upon human disease is another and at present unsolved question. To the two filtrable viruses of which at present most is known—those of vaccinia and of symptomatic herpes—it apparently bears no relationship. In spite of these results, negative so far as varicella is concerned, the work of Dr. Rivers and Dr. Tillett is of the utmost importance, for they have succeeded in demonstrating yet one more of the filtrable viruses; how many more may exist and what are their relationships to each other and to human disease no one can yet even guess, but their nature and distribution is obviously a problem which cries out for elucidation.

In the same volume of studies from the Rockefeller Institute Dr. E. N. Cowdry and Dr. F. M. Nicholson make a further contribution having important indirect bearings upon this question. These authors show that in a certain proportion of supposedly normal laboratory mice encephalitic lesions are present in association with infection of the brain by a protozoan parasite. Attention has been drawn to this same phenomenon in the case of rabbits by a number of authors, including Da Fano in this country, within the last few years. A peculiar point, and one to make epidemiologists ponder, is that this widespread incidence of protozoan encephalitis affecting rabbits and mice in laboratories throughout the world is a new thing. The condition is known to have existed in 1921, but there is good reason to believe that it has appeared since 1917. It is apparent that not only the human mammal has been afflicted with new plagues in the last seven years.

SURGICAL HEADACHE.

THERE appear to be a certain number of headaches which are amenable to surgical treatment. The characteristic nature of such headaches is that they are usually severe, subject to exacerbations, increased by movement or excitement, and frequently limited to definite areas of the head. A. R. Campbell and C. K. Fuller¹ have recently drawn attention to this variety of headache which they classify as being due, with few exceptions, to pressure, inflammation, or the two combined. They point out that the principle of referred visceral pain, so thoroughly applied in abdominal surgery, should be extended to cover intracranial lesions. The symptom-complex of neuralgia, superficial tenderness, and segmental headaches should be looked upon as indicating some localisable intracranial lesion. They classify these segmental areas, which overlap to a certain extent, as frontal, temporal, vertical, parietal, and occipital, and for each of these situations is set out a list of lesions which may cause a headache. For example, the causes of a vertical headache are described under the headings of posterior ethmoid sinus disease, sphenoidal sinus disease, enlarged turbinates, deviated septum, middle-ear disease, depressed fracture, tumour, cyst or abscess at the base of the brain, pituitary disease, and aneurysm. In some of these lesions the headache may be unilateral or it may be universal, but headache from the same lesion is stated always to occur in the same situation in the same patient. Intervals of freedom from the pain may occur and it may only come on during certain times of the day or night. The application of adrenalin and cocaine to the nose may relieve the headache, indicating that nasal or sinus disease is the cause, and such headaches usually become worse during acute nasal catarrh. The use of the ophthalmoscope is advocated as essential in cases of severe continued headache, so that optic neuritis may be detected early, before irreparable damage has been done to the vision. It will be seen that the complaint of headache must very frequently come under the surgeon's notice, and Campbell and Fuller consider that there is need for greater emphasis being laid upon the differential diagnosis of this most common symptom.

¹ Canadian Med. Assoc. Jour., February, 1925, p. 144.

THE WORKMAN AND THE HOSPITAL.

IN the annual reports of hospitals which are just now being presented in such profusion to their supporters, nothing is more significant than the almost unbroken series of records of the success of workmen's hospital funds. Wherever they have been established they have almost invariably produced results that at the worst have been satisfactory, and at the best have been brilliant. It is a mistake to suppose that this method of bringing under contribution the classes which most frequently have resort to hospitals is something new, a product of the after-war crisis in hospital finance. These funds have, no doubt, greatly increased in number during the last few years, but a fair proportion of them have moved well into maturity. Thus the Workpeople's Hospital Fund at York was started nearly a quarter of a century ago. Last year it provided the York County Hospital with one-third of its income, and since it began it has contributed a total of nearly £60,000. This is merely one outstanding instance among many. All over the country we hear of "record" years of similar funds, of totals nearly doubled in 12 months, of the readiness of the artisan to take his share of the burden of maintaining the voluntary system. In more than 1600 places of business in Manchester and Salford there are penny weekly collections, and similar schemes are at work not only in many other large towns but in rural districts. Organisation and time are the two essentials of success—experience shows that enthusiasm is engendered without difficulty. In view of the vast amount of re-building and re-equipment which the hospitals, having, broadly speaking, surmounted their current difficulties, now have to face, these funds are certain to be of vital importance in the near future. They may not be able to provide the tens of thousands of pounds required for the provision of new wings, but they can, and do, act as splendid stimulants to the entire community.

VACCINATION AGAINST TUBERCULOSIS.

IT has long been the aim of many workers, and particularly of the French school led by Calmette, to obtain some method of vaccination against tuberculosis which should imitate in a scientific manner the natural process of vaccination by means of which so many individuals, inoculated by a small dose of tubercle bacilli in childhood, develop a complete and lasting immunity to the disease. Indeed, so effective is this natural process in the majority of cases that the fear has been expressed that if we completely stamped out bovine tuberculosis in this country we should remove the chances of this inoculating dose of tubercle bacilli from many children and tend to rear a race which would present a "virgin soil" to infection in later life with disastrous consequences. But the dose of bacilli obtained by the ingestion of dairy produce contaminated by bovine tuberculosis is very uncertain and for some children unfortunately proves fatal. Calmette has therefore devoted a long period of time to producing a type of tubercle bacillus which could be inoculated in a living form without giving rise to any local or focal lesions. After 230 successive cultures on a medium consisting of 5 per cent. glycerine potato and ox-bile, over a period of 13 years, he believes he has obtained a tubercle bacillus which is living but not "tubercul gene."¹ This bacillus, known as the bacillus-Calmette-Guérin (B.C.G.), is apparently avirulent, while it secretes a "normal" tuberculin. Weill-Hallé and Turpin² have employed the bacillus for vaccination since 1922 in 300 children born into tuberculous families. Following Calmette's teaching that the ingestion of tubercle bacilli is the principal mode of infection in the natural process, they give the B.C.G. by the mouth in doses of 1 cg. half an hour before food for three doses either on the third, fifth

¹ Calmette and others: Presse Médicale, July 2nd, 1924.

² Weill-Hallé and Turpin: Paris Médical, Jan. 3rd, 1925.

and seventh or the fourth, sixth and eighth days after birth. Treatment at this early age is important, for, according to Calmette, this method should only be used where there is no chance of previous infection with the tubercle bacillus. The device is usually employed where tuberculous parents refuse to be separated from their children. Of the first 178 cases, which have been closely followed up with monthly medical examinations, nine have died—a mortality rate of 5 per cent., and the remaining 169 continue to be well and healthy in spite of the fact that they are subject to constant infection in the home. In this country Eric Pritchard has reported somewhat similar work.³ He has been using prophylactic injections of tuberculin at weekly intervals for the first six months of life in the case of infants born into a tuberculous environment. He has thus treated 40 cases during the past 13 years and all are alive and well, the eldest being 12 years old, although in each case either the mother or the father was suffering from active tuberculosis. It is obviously too early yet to estimate the value of such prophylactic measures, but the results both here and in France will be watched with interest.

TRADE DERMATITIS.

AN article on Lime Dermatitis by Dr. W. J. O'Donovan, which we publish on another page of this issue, calls attention to an interesting form of trade dermatitis—an important section of occupational disease. It is difficult to estimate accurately the extent to which trade dermatitis is responsible for attendances at clinics for diseases of the skin; it differs in different clinics according to the occupations followed by the local population, and variations in the figures given by different authors must occur. Lane⁴ considers that from 4 to 5 per cent. of all patients admitted to the skin department of the Massachusetts General Hospital were suffering from lesions due to their occupation. Fordyce⁵ gives 2 per cent. for his own clinic, but quotes H. H. Hazen, who considered that 20 per cent. of his cases were due to the patients' occupations. Frank Crozer Knowles,⁶ in a review of nearly 25,000 skin cases, concluded that about 16 per cent. of all skin cases were due to the patients' work. MacLeod, in his textbook, "Diseases of the Skin" (p. 283), says, "a considerable percentage of the skin cases in adults in hospital practice are due to their occupations." He gives a list of 33 common occupations in which dermatitis is liable to occur, whereas Herxheimer⁷ enumerates 74 trades provocative of eczematoid dermatitis, and the trades included in Prosser White's "Occupational Affections of the Skin" (second edition) must number well over 100. As would be anticipated from these figures, and as is confirmed by fact, new causes of dermatitis are constantly arising owing to the invention of new chemical processes or the modification of old ones. A comparatively slight change in a process may make a large difference in the incidence of dermatitis caused by it.

That a dermatitis is one of occupation may be easily missed in diagnosis, because many different agents produce a dermatitis superficially similar, or one resembling some common skin condition not regarded as due to an external irritant—witness the first case of lime dermatitis quoted in Dr. O'Donovan's article, where, in the original attack, the patient's trouble was diagnosed as seborrhœic. Secondary infections with staphylococci or streptococci are frequently superimposed on a dermatitis originally due to occupation and still further confuse the issue. Some types of trade dermatitis are, however, well marked and easily recognisable when once known to the observer; such are "chrome sores," "lime holes,"

"pitch skin," "tar acne," and "mule-spinners' cancer," whose names suggest their origin. The agents causing trade or occupation dermatitis are numerous, and many attempts to classify them satisfactorily have been made by different authors. They may, for instance, be divided into physical, chemical, and parasitic groups. The physical would include such causes as mechanical injury, wind, light, X rays, extremes of heat and cold, of dryness and moisture. The chemical group is by far the largest and requires much subdivision; it includes both organic and inorganic chemicals and the toxins of certain plants and trees. The parasitic group includes infections due to bacteria and fungi, and the attacks of animal parasites, such as mites. Causes coming under two or more of these headings may act together. The points of attack of the chemical irritants are almost invariably, in the first instance, the mouths of the hair follicles, the sebaceous glands, and the sweat pores, with, in addition, the natural furrows on the skin and any accidental abrasions. The maceration of the epidermis by the action of alkali materially increases the danger of attack by chemicals. In many industries certain workers seem to be naturally immune to the risks involved, others acquire an immunity, and it is important for all concerned for the employer to build up an immune personnel by the discharge of workers whose skins prove sensitive. In some cases, however, in workers who have appeared immune for years, the immunity breaks down under temporary ill-health or excessive exposure to the irritant. The treatment of trade dermatitis resolves itself primarily into removal of the patient from exposure to the irritant, and secondarily in protective or antiseptic treatment of the lesions, the possibility of malignant disease being remembered. The adage, "A stitch in time saves nine," applies with particular force to trade dermatitis, where early and accurate diagnosis is of such vital importance if the patient is to be speedily cured.

THE THERAPEUTIC ADMINISTRATION OF GLUCOSE.

CONSIDERABLE interest has been aroused by an article on the oral administration of large quantities of glucose, by Dr. T. Izod Bennett and Dr. E. C. Dodds, which appeared in THE LANCET of Feb. 28th. It will be remembered that these workers, impressed by the physical transformation often produced in diabetics by the administration of insulin, sought to ascertain whether improvement in the nutrition of wasting non-diabetic patients could be obtained by feeding them with glucose, possibly in association with injections of insulin. Benefit could not, of course, be anticipated if the ingestion of large quantities of glucose were found to give rise to corresponding glycosuria; but preliminary experiments on 15 normal volunteers showed that up to 500 g. of glucose in one dose could be taken without more than a trace of glycosuria. Clinical observations were then made on cases of acute infection, cases where hamatemesis was the main symptom, and cases of marked under-nutrition. Distinct benefit appears to have resulted from the addition of large quantities of glucose to their diet and no ill-effects were observed. The glucose used by the authors was commercial glucose (glucose B.P.), which they describe as a viscid syrup, prepared by the hydrolysis of Indian corn or other cereal starch with mineral acids. Glucose B.P. is guaranteed to contain less than two parts per million of arsenic; a number of samples from various sources gave negative reactions to Marsh's test. The cost of this commercial glucose is only about 6d. a pound, and when one pound is dissolved in a quart of water to which two lemons are added it makes a palatable drink. The price of this product is contrasted by the authors with that of pure glucose, which, they state, costs about 8s. 6d. a pound, whether in crystalline or anhydrous form. More than one of the large drug manufacturing firms have written to inform us that this statement stands in need of revision. The

³ Brit. Med. Jour., August 30th, 1924.

⁵ Jour. Amer. Med. Assoc., 1912, lix., 2043.

⁶ Ibid., 1917, lxxviii., 79.

⁷ Deut. med. Woch., 1912, xxxviii., 18.

large hospitals purchasing the substance in hundred-weight quantities are able to procure it at less than half the price mentioned, while the rate even for small quantities is not much more than half this price. The statement that "pure glucose is little used save in chemical laboratories" has also been questioned, since apparently there is a demand for this product in considerable quantities from a large number of hospitals and public institutions. Commercial glucose is a heavy chemical; it is well known that the drug firms do not manufacture heavy chemicals and are therefore powerless to vary them or to control their composition. The difficulty of precise analysis of commercial glucose is admitted; it is not a single substance, but is a very variable mixture of glucose, dextrines, and other carbohydrates, and, according to one of our correspondents, it invariably contains objectionable quantities of sulphites. Pure medicinal glucose, on the other hand, is a fine chemical, manufactured by the fine chemical makers under rigid conditions of control, and the composition of it can be guaranteed. We are not convinced that the oral administration of the crude commercial product is likely to do any harm, but are glad to give publicity to the fact that pure medicinal glucose can be obtained cheaply by those who prefer to use a finer product.

PLAGUE IN THE ORANGE FREE STATE.

OUR South African correspondent states that the presence of plague in the Orange Free State is undoubted, and creating uneasiness. The Union Department of Public Health, in a bulletin published on Feb. 18th, reported nine cases in Europeans of plague in the Boshof district of the Orange Free State. Of these cases, four proved fatal. There was also one fatal case on another farm in the same district. The investigations carried out in the Boshof district by a health officer of the Department of Public Health have now resulted in the confirmation of the diagnosis of the disease being plague. A big campaign against plague, conducted along education lines, has been entered upon at Kimberley. It will embrace the extensive areas of Griqualand West, the Orange Free State, and the Cape Province. The Red Cross Society is coöperating with the Union Public Health Department to this end, and has placed a huge motor demonstration van at the disposal of the Department. Lectures and demonstrations are being given by Mr. Austin Roberts, of the Transvaal Museum.

THE PHILOSOPHER LOCKE AND THE UPBRINGING OF CHILDREN.

MODERN pedagogues hold that to spare the rod does not so much spoil the child as save him from a group of the more startling "complexes" that may dog his future. The attitude of many up-to-date instructors of infancy is not to impress upon the *tabula rasa* of the infant mind such forms and habits as appear proved by experience to be helpful, but rather to stand aside and watch a miracle unfold from within. Opportunities of studying the evil effects of the "impression" method have been given to many medical men, while no modern book of memoirs fails to bewail it in the interests of hero or heroine under the name of the "repression" method; a future generation will have to examine the results of a training by "expression." Meanwhile many parents of to-day stand bewildered.

That the subject is one of high interest to medical men was shown by the size of the audience which gathered at the social evening of the Royal Society of Medicine on Monday last to hear Dr. H. C. Cameron expound the views of Locke the philosopher. The philosophical and political achievements of Locke have to some extent obscured in the public mind the fact that he was an active member of the medical profession. In the intervals of writing metaphysical treatises, restoring the finances of this country after the great Revolution, taking a

part in the foundation of the Bank of England, instituting reforms in the administration of the Poor-law, and assisting in the framing of the Constitution of the State of Carolina, Locke found time to conduct a successful general practice. Indeed, for such a life, as one of his biographers has remarked, there would be no better preparation than an acquaintance with the "fugitive and often equivocal phenomena of disease which resemble more nearly the phenomena about which metaphysics, ethics, and logic are concerned" than do the more precise investigations of physics or mathematics. That he was no mean surgeon also is shown by his treatment of that "imposthume in the breast" from which Pepys records Lord Ashley to have suffered in June, 1668. "He hath been fain to be cut into the body," remarks Pepys, and it was Locke who undertook this operation, sterilising the skin by free application of the cautery and evacuating what we now know as a hydatid cyst through a silver tube. When such a man as Locke turned his attention to the problem of the upbringing of children it might safely be assumed that his opinions would be worthy of note, and his little book on the subject went through 12 editions in some 50 years. He knew that crying babe who renders the night hideous, the neighbours furious, and the doting parents distraught. Crying, he observed, was of several sorts, but the worst of all was the "stomachful cry," the cry purposive, the deliberate attempt to disturb and distress the parent. Such children are invariably the offspring of parents who are most susceptible to the disturbing effects of such crying. It is remarkable how a child divines the weak point in its mother's armour and then seems impelled to keep on exploiting that discovery, like the insane patient who appears forced to wound most those whom he most loves and depends on. For excessive corporal punishment Locke had little use. Children are susceptible, earlier than we think, he said, to praise and commendation, and much may be done to mould them to the parent's will by a consistent attitude of pleasure or displeasure according as the conduct is right or wrong. Blows should only be administered when the child offers a challenge—what the modern psychologist would call a "power claim"—"the obstinate or stomachful cry should by no means be permitted," least of all should a hasty correction be allowed to end in such obstinate bawling, for then the good of the punishment would be all undone. Chastisement should be delivered calmly and with observation of its effect on the mind and brought to an immediate close when the child has been rendered pliant. "To put their bodies in pain without doing their minds any good is more cruelty than correction."

Locke knew also that older problem child, the subject of those familiar school reports: "Could do better," "Lacks concentration," and "Will not attend"—the child whose zest is choked by the consciousness of his failure at everything and his interest thwarted by the very eagerness of his efforts to attend. Locke understood and pointed out how hard it was for any to learn when pressed by strong emotion, such as fear. "It is impossible," he said, "to trace fair or regular characters on a trembling mind as it would be to trace them on a trembling paper." In this connexion Dr. Cameron recalled aptly the case of a surgeon, a friend, who brought to his consulting room a small son who did not progress at school. The surgeon began to appreciate the difficulties of the child's situation when it was suggested to him that a similar régime to that of the school might be introduced at his hospital; when the governors might summon him periodically to the board room, intimate that they were dissatisfied with his work, that the weekly lists of operation results showed his name invariably lower than that of his colleagues, that his marks for asepsis were consistently poor, and, as a final suggestion, that he might go to the hospital on Saturday afternoon and do 50 hernias as an incentive to future effort. The parable worked its effect.

PREJUDICE AGAINST WELFARE CENTRES.

UNDOUBTEDLY prejudice sometimes exists, generally in rural districts, against the valuable ministrations of welfare centres. It frequently takes the form of resentment by mothers against interference in behalf of their children, but the usual cause of friction between a mother and a welfare centre has its roots in the belief that a woman who has had children must know how to bring them up. Last week at Loughborough an unfortunate mother, at an inquest upon her child, in whose behalf the ministration of the welfare centre had been refused, defended her inaction upon exactly that ground, when the coroner told her that she had erred in relying upon her own judgment. The jury rightly returned a verdict of death from natural causes, but it is a little surprising that the benefits that can be derived from the systematic work done at welfare centres are not more immediately recognised. Undoubtedly some welfare centres are better managed than others, and now and again absence of tact on the part of some welfare worker may alienate the sympathy not only of those for whose use the centres have been designed, but of the medical men in the locality. Of such a situation, however, we do not hear often, and when it has been created it should be capable of quick remedy. And against the views of mothers who employ as proof of their experience the classic argument, "I've had six children and buried four," can be set the enlightened gratitude of very many homes.

AUGUST VON WASSERMANN.

FROM Berlin comes the announcement of the death, on March 16th, of August von Wassermann, whose name is so familiar in the medical vocabulary of the world. Wassermann was born in Bamberg, Bavaria, in 1866, and studied medicine in Munich, Strasburg, Vienna, and Berlin, obtaining his degree at the University of Strasburg in 1889. In Berlin he was one of Koch's pupils, and in 1891 became his assistant at the Koch Institute for Infectious Diseases (with which institution he remained associated throughout his entire career), and he was appointed as physician to the staff of the Royal Charité Hospital. In 1898 he obtained a titular professorship and settled at Berlin University as lecturer, being appointed ordinary professor in 1903. Four years later he was placed in charge of the University department for therapeutic and serum research, and in 1913 he became director of the Kaiser Wilhelm Institute for Experimental Therapeutics at Dahlem, near Berlin. Wassermann's great contribution, along with Neisser and Bruck, to medical science, the discovery of the complement-fixation test in syphilis which bears his name, was made in 1906, one year after Schaudinn had found the parasite of the disease. The value of this test has been enormous. The grounds upon which Wassermann and his colleagues based their experiments were rigidly scientific. In accordance with the observations of Bordet and Gengou they deemed it necessary to use as antigen an extract of syphilitic liver, and they assumed that a positive reaction meant the presence of specific antibody in the blood of the patient. But it was soon found that the specific antigen was unnecessary. An alcoholic extract of normal liver or heart, even from a guinea-pig, was found to serve just as well, and, indeed, solutions of known chemical composition—e.g., of lecithin and cholesterol—were proved capable of acting as antigen, and this without any impairment of the diagnostic value of the test. Thus the scientific basis of the reaction was shattered, but the test, interpreted empirically, did not lose validity. The investigation has since been taken up by biochemists, and it is possible that this serological problem may ultimately receive a physico-chemical explanation.¹ Syphilis

¹ THE LANCET, 1920, ii., 78.

was not the only field in which Wassermann conducted his researches. Early in his career, together with Ehrlich, he studied the antitoxin treatment of diphtheria, and he also did important work in connexion with inoculation against typhoid, cholera, and tetanus. Latterly he had been working on tuberculosis, and at the German Medical Congress in October, 1924, he reported on the possibilities of sero-diagnosis in cancer. A fluent and lucid writer and lecturer, Wassermann made many valuable contributions to scientific and medical literature.

THE LONDON INSURANCE COMMITTEE
IMPASSE.

IN THE LANCET of March 7th we reviewed an embarrassing situation arising from the withdrawal of the medical members from the deliberations of the Medical Service Subcommittee of the London Insurance Committee. The Subcommittee has been unable to obtain a quorum for three months and important work has been held up. At a special meeting of the London Insurance Committee held on March 14th the following resolution was carried:—

That, in order to overtake the arrears of work existing at the present time and subject to the consent of the Minister of Health, the Insurance Committee for the County of London do constitute a second Medical Service Subcommittee to sit and act concurrently with the first, such subcommittee to be appointed purely as a temporary measure and in no case for a period beyond June 30th, 1925.

One of these subcommittees has as medical members Dr. H. J. Cardale and Dr. E. A. Gregg, as the representatives of the Panel Committee, and Dr. T. M. Ness, as the representative of the Local Medical Committee, and will function under the chairmanship of Mr. David Davis. The medical members of the other subcommittee are Dr. R. L. Bell and Dr. W. C. Goodden, representing the Panel Committee, and Dr. K. McFadyean, as the representative of the Local Medical Committee, and the suggested chairman is Mr. H. Mills. It is hoped that the appointment of a second subcommittee will mean that the accumulated work will speedily be dealt with.

THE delivery of the third Lettsomian Lecture by Sir Bernard Spilsbury has been postponed.

THE Wellcome Historical Medical Museum will be closed for cleaning and decoration from April 1st to April 30th inclusive.

DONATIONS AND BEQUESTS.—Miss Rose Esther March, of Leeds, left £21,000 for charities, including £2000 each to the Leeds General Infirmary and Leeds Maternity Hospital, £1000 Leeds Public Dispensary, £500 each Leeds Women's and Children's Hospital, Leeds United Institution for the Blind, Deaf, and Dumb, Leeds District Nurses' Institute, Church Army Home, Leeds, and several benevolent institutions.—Lord Bearsted has promised to give £10,000 for the provision of a new clinical theatre at the London Hospital. The income of the balance not required for the cost of the theatre to be used for purposes of research and the investigation of disease. Mr. Alfred Williams has also promised £10,000 in memory of his son, Owen, the income of this money also to be spent in the investigation of disease.—Mr. Robert Henry Carpenter, solicitor, Bristol, left £500 each to the Royal Infirmary and the Bristol General Hospital, and £250 to the Bristol Dispensary.—Mr. John Macfarlane, Brough, Yorks, left £1350 each to the Port of Hull Society's East Coast Mission and Sailors' Orphan Homes, and the General Infirmary, Perth, £500 to the Young People's Christian and Literary Institute, Hull, £450 to the Hull Infirmary, and £250 to Dr. Barnardo's Homes. After the fulfilment of other bequests, half of the residue of the property, which was of the gross value of £18,356, will go to the Hull Royal Infirmary.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXIV.—THE TREATMENT OF SPRUE.

SPRUE, formerly, and, in fact, until comparatively recently, a disease of the tropics, is coming to assume an ever-increasing importance for medical practitioners in this country. Whether the disease ever occurs in an individual who has not at some period resided in the tropics is not certain, but in the same way as pellagra was found to exist in England, when it was looked for, so may it turn out to be in the case of sprue. Apart from this, however, patients return home from the tropics in large numbers on account of sprue; after apparent cure they relapse while at home, for, at all events, until recently, a sprue patient was always advised against returning to the tropics; and, lastly, cases undoubtedly occur where persons who have lived abroad enjoying good health begin to show symptoms of the disease months, even years, after they have retired and settled down at home. For these reasons it is important that the practitioner at home should know something about sprue, and, further, that the diagnosis of the condition should be based upon a sure foundation. This point is essential, since some of the symptoms present in true sprue, such as loss of weight and fatty diarrhoea, are found in other diseases, and also, a matter of greater moment, because recent, rational methods of treatment bring about a rapid and, so far as we can judge at present, a permanent cure if the case is taken in hand early—a marked contrast to what occurs under the older, empirical methods of treatment, which lead usually to temporary improvement only, with the risk of relapses and in many cases to death, with symptoms indicative of pernicious anæmia after a varying period of partial invalidism.

Empirical Methods.

The empirical methods of treatment most generally employed are as follows:—

Dietetic.—Some patients are kept on milk, at first solely, later chiefly, for weeks, and even months, and on leaving hospital are given a fairly rigid dietary, which they are warned against infringing at their peril. Others improve on the Salisbury treatment (hot water and scraped meat), being unable to tolerate milk in the quantities necessary to form the main article of food. Whichever line is adopted it is found that mixed diet in the early stages is not good. Others, again, pin their faith to liver soup, and some patients may even come to like it, but man cannot live by soup alone. It is, perhaps, given on the idea that bile is absent from the white frothy stools, and that the hepatic functions may be stimulated thereby. The "strawberry cure" must also be mentioned under this head. Well-to-do patients have been known to travel about from place to place in order to keep in touch with the fruit; poorer persons who have to stay in England take strawberries in season, then pass on to raspberries and next to loganberries and, when these can no longer be obtained, to bottled fruit and strawberry jam until the next crop is gathered. As the fruit constitutes only a small part of the dietary, its value in sprue cannot be accurately estimated.

Vaccines.—The administration of these is in some cases attended by good results; the rationale of this is explained later. That the organism cultivated is not the one causative of sprue as an entity is proved by the fact that different vaccines will in various hands produce equally beneficial effects—monilia, coliform bacilli, streptococci—while others record no benefit from the use of any of these.

Drugs.—Santonin was in considerable vogue for a time, but it was said to be a requisite that the drug must have been sent on a voyage to tropical countries in order that the white crystals might take on a brilliant yellow by exposure to tropical sunlight, otherwise it was ineffectual. It is now but little used, and is most uncertain in its effects. Emetine, also, has been, and is now, used in sprue, and some cases with sprue symptoms undoubtedly improve and even get well with it; in others it proves quite useless. Many sprue patients give a history of previous dysentery, and it is probably some residual effect of that disease which the emetine clears up, since dysentery is one of the conditions whose later symptoms may in some respects resemble sprue. Such cases as have come within the knowledge of the writer do not answer to the laboratory tests for sprue.

Calcium-Parathyroid Treatment.

The most recent form of treatment, based on the results of laboratory tests, is that by calcium and extract of parathyroid gland. This is, at least, founded on rational grounds and the progress and results of the treatment can be tested in the laboratory. The fatty diarrhoea, the cramps which are often present, the cedema and tetany seen in late and severe cases are some of the symptoms which may be ascribed to faulty calcium metabolism. The total calcium in the blood is, however, normal or very nearly so, hence absorption of calcium is little if at all interfered with. It has been shown that, normally, calcium is present in the plasma in two forms: some 6 mg. per cent. (i.e., per 100 c.cm.) being in what H. W. C. Vines¹ describes as the free or ionic form, and readily precipitable by its chemical equivalent of ammonium oxalate solution; the remainder, 4 mg. or a little more, is bound and requires, perhaps, three times its equivalent. This he calls the combined or coagulative calcium, since it is closely concerned with blood coagulation. Normally, when coagulation takes place, practically the whole of the calcium is found to be in the ionic form in the serum. In sprue, but in no other sprue-like conditions in which similar tests have been carried out, the ionic calcium in the serum is reduced, in severe cases, by as much as 30–40 per cent. Although absorption of calcium does not appear to be interfered with to any extent, since the total is within the normal limit, the regulation of this element is upset. By flooding the system with calcium, as by giving large quantities of milk, by the use of pulvis Bataviæ, by the administration of powdered cuttle-fish shell (as used in China), this deficiency is temporarily made good and improvement ensues, but, and this is the important point, the improvement is not stable. The regulator of calcium metabolism is believed to be the parathyroid glands, and this is borne out by the fact that if parathyroid extract is given in doses of one-tenth of a grain twice daily, the symptoms of sprue have been shown to clear up with marvellous rapidity. The ulcerative stomatitis may disappear in ten days or so, the diarrhoea is replaced by constipation, the colour begins to return to the stools in two to three weeks, the patient puts on weight, often 3 to 4 lb., sometimes as much as 7 lb., in a week by the end of a month, and his sense of well-being is restored.

The technique of estimating the ionic calcium by Vines's method is as follows: Blood is taken in a glass tube, about 1.5 to 2 c.cm., and allowed to clot. The serum, of which about 1 c.cm. is needed, is then separated and heated in a water-bath to 56° C. for an hour. The steps in the test are three: In the first, by adding fixed amounts, 4 vols., of various dilutions of ammonium oxalate to 10 vols. of fresh normal blood (usually that of the person carrying out the test) and placing the mixture in the thermostat at 37° C. for ten minutes, that strength of oxalate is found which just prevents clotting under the terms

¹ The Parathyroids in Relation to Disease, 1924, Arnold.

of the experiment. The next step is to find out, by adding 2 vols. of various dilutions of calcium chloride to fresh arrangements of the above mixture (4 vols. of the determined oxalate dilution and 10 vols. of blood), what dilution of calcium chloride just suffices to bring about complete clotting of the blood. The third step consists in carrying out tests similar to the last but replacing the calcium chloride solution by the same volume of dilutions of the patient's serum, prepared as previously described. By a calculation the calcium content of this serum is thus determined, and in normal subjects will be found to be somewhere between 10.4 and 11.4 mg. per 100 c.cm. In severe sprue it is about 6.5 mg., and after the treatment to be detailed shortly is begun, if this test of blood is carried out weekly, a steady progress is noted, till, at the end of four to six weeks, it is found to reach normal. The theory in part is that one of the actions of the parathyroid glands is to counteract intestinal toxins; that it carries on this work until the toxins are too great for it to cope with. Under these conditions, if the toxins can be reduced, as by careful dietetic regulation, the glands can recover and perform their function again, at least for a time. If, by good fortune, one of the chief causative organisms is isolated and a vaccine made, the administration of this may relieve the gland for a time, hence the good results of some vaccines in some cases and of other vaccines in other cases, as mentioned above; hence, also, the failure of vaccines in the hands of many, some other than the toxin-producing organism having been isolated.

The usual line of treatment by this most recent method is to put the patient to bed for the first 14 days, allowing milk only, beginning with $3\frac{1}{2}$ to 4 pints a day, taken warm (not hot) with a teaspoon, at regular intervals, and increasing by $\frac{1}{2}$ pint in the 24 hours, till at the end of the fortnight 7 to $7\frac{1}{2}$ pints are taken daily. Calcium lactate is also given in cachets containing 15 gr. each, thrice daily, and parathyroid extract gr. 1/10 twice daily. It is absolutely essential that the extract be free from thyroid. If there is constipation a small dose of liquid paraffin is probably the best aperient. From the tenth day onwards some plain biscuits may be allowed, such as water biscuits or Mellin's food biscuits. By this time the ionic calcium has probably increased to between 7 and 8 mg. per cent., and gradual increase in food may be allowed and the patient permitted to be up for an increasing time each day. At the end of three weeks the patient, unless a very severe case or one of long standing, can take milk-puddings, eggs, fish, potato, carrot, bananas, and in the fourth week chicken and non-acid fruits. The calcium can be reduced in the third to fourth week and probably stopped altogether at the end of the fourth. The parathyroid extract should be continued in full doses till the fifth week, then reduced to half doses for a week, and in most cases further reduced until it in turn is stopped altogether at the end of six to seven weeks. This, however, can only be gauged with certainty by the blood test, and the drug must be continued until this shows that the ionic calcium has reached the normal.

It will be found that any return of symptoms, whether due to dietetic or other indiscretion, will be evidenced also by a fall in the ionic calcium, hence the enormous value of the test as a gauge of progress in this disease.

Though it is, perhaps, too early to claim permanency of cure, several of those who had been invalided home and forbidden to return to the tropics have, nevertheless, gone back and remained perfectly well, and equally good results have been recorded of patients treated in the endemic centres of the disease.

H. HAROLD SCOTT, M.D., M.R.C.P. Lond.,

Milner Research Fellow in Comparative Pathology, London School of Hygiene and Tropical Medicine.

Special Articles.

ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

FURTHER SITTINGS.

(Continued from p. 512.)

THE Commission resumed its sittings on March 10th under the chairmanship of Mr. H. P. Macmillan, K.C.

Evidence of the Mental Hospitals Association.

Alderman J. G. Taggart (Liverpool) and Alderman Sir William Hodgson (Crewe) attended to give evidence on behalf of the Mental Hospitals Association.

Alderman Taggart said the body he represented wished to eliminate the element of pauperisation from lunacy administration, remarking that but for their mental illness less than 5 per cent. of the persons concerned would be pauperised. Cases of incipient insanity should be admissible to hospitals which were supported by the public health authority; mental illness should be provided for by public health authorities, in the same way as tuberculosis and venereal disease. These clinics would be in the nature of receiving houses, and would relieve the asylum population. It might need but little structural extension to existing hospitals. In each county, or in the less populous areas each two or three counties, there should be such a clinic, the present 50 per cent. grant for present clinics being extended to mental disorders of this nature. He suggested a modified form of provisional order, more on the lines of that required in the case of infectious diseases. Though himself a magistrate, he thought the governing authority should be medical. Also, in the matter of discharge, the medical superintendent's views should never be over-ridden by visiting committees; in one instance ten discharges took place under these circumstances, and most of those patients had to return.

Sir William Hodgson supported the idea of giving early treatment of mental cases in clinics. In the case of Cheshire, the proximity of Liverpool and Manchester would facilitate a smooth working of such a scheme. No man should be appointed a medical superintendent unless he had special psychological qualifications. To secure such diplomats was now much easier than it had ever been before. Owing to the depressing character of the medical work, he thought there should be interchange of service; also, there should be a shorter period of service for them, and the retiring age should be younger than at present. The administrative business of a mental hospital should be, in his view, entirely separated from the medical side of the work.

The Mental Treatment Bill.

The witness said that he approved of the general principle embodied in the Mental Treatment Bill. The Mental Hospitals Association had passed resolutions to that effect. That body considered that for a long time there had been necessity for such a Bill. It might have relieved many cases which in acute bodily illness were badly affected temporarily in mind.

The Chairman said he took it that Sir William Hodgson wanted to fill up the gap in treatment by some such scheme as that embodied in the Mental Treatment Bill, and the witness replied that this was so, but he disagreed with some of the machinery and methods proposed. He took exception, as did both the bodies he represented, to the clause dealing with the constitution of visiting committees, and particularly the provision for cooption. They said that these visiting committees should be strictly representative of elected bodies, as that was the only representation which was of value.

The Chairman pointed out that there might be persons interested in the welfare of the mentally afflicted and who were prepared to devote much time and work to the subject, and who, therefore, might be very useful in that branch of work.

Sir William Hodgson replied that that was always the argument used in favour of coöption. He had had much experience of coöption on public bodies, and he could not say it had been entirely of a satisfactory character. Some of the coöpted members were very enthusiastic persons, but in the promotion of the interests on particular lines the costs were not considered. As a rule, the most expensive members were the coöpted members. Moreover, these people were very easily approached by sympathetic appeals made on behalf of suffering people. Unless they had a full responsibility as to cost these appeals were, mostly, likely to succeed.

Lord Russell pointed out that coöption was a permissive function.

Asked about the influence of ladies as coöpted members, Sir William Hodgson said they had great powers of persuasion over the council.

Miss Symons asked whether one or two women were likely to persuade so many men, and the witness replied in the affirmative, remarking that he had often seen it done.

The Chairman suggested that the presence of women on these committees was very desirable as they had a better knowledge of household concerns and were probably better critics of administration, and he asked how they could be secured without coöption.

The witness replied that on most authorities women were now coming on in an elected capacity, and both his Associations agreed to women being included when they were elected by the ratepayers.

Lord Russell suggested that if there had been women on the visiting committee of Prestwich Asylum many of the criticisms of that institution might have been avoided.

The witness replied that he did not think he ought to be asked about Prestwich.

The witness was then asked his views as to the prosecution of research at asylums, and the line he took was that the impetus for research among workers in asylum laboratories ought not to be smothered by interference from the Board of Control or other central authority. He contended that the inventive discovering mind was of a peculiar type, and was not necessarily revealed in team-work. He favoured strongly giving asylums with well-equipped laboratories a free hand in their researches.

The Chairman suggested that the requirement of the approval of a central body would prevent unnecessary duplication of research and undesirable overlapping. It also might project research into one particular class of diseases in one centre and another in another centre, and not only avoid overlapping, but help to concentrate the work. The representatives of the ratepayers of a particular district in which an asylum was situated should have the power, he thought, to decide unhampered what researches should be carried out, as the ratepayers paid for it.

Sir Humphry Rolleston asked whether the Board of Control had exerted any action which was derogatory to research.

The witness answered in the negative, but said it was because they had not the power, and they were anxious to get that power.

Sir Humphry Rolleston then asked whether it was not an advantage to have the advice of the Board of Control, and their function of ascertaining what work had been done.

The witness said he did not think so. When the Association discussed the matter it said it was not in favour of having State grants if that would mean more control by the Board of Control. If it were said that there would be larger grants but more grip on the work being done, the attitude was "Take your grants, we would rather not have them."

The Chairman asked whether the witness's view was that there should not be interference, but some coördination, and the reply was, "We welcome advice, but we say the tendency is to be too much governed." He went on to say that the central body had done nothing for research.

The Chairman pointed out that the Board of Control had to deal with not only large up-to-date laboratories and asylums, but with places where the zeal was not so keen.

The witness replied that the Mental Hospitals Association was brought into being for the purpose of meeting and discussing the problems connected with the various asylums, and to deal with difficulties.

Asked as to his views on the appointment of district commissioners and inspectors, he said it was the multiplication table in the wrong direction.

Sir Humphry Rolleston asked whether the witness thought the Board of Control should be dispensed with.

Sir William Hodgson replied that he did not think anything he had said called for that question, but he would reply that he did not think they were doing any effective good work, and he would not be sorry to see the Board of Control scrapped.

The Chairman asked whether if the Board of Control were scrapped some other body should not be substituted for it, and the witness replied that he thought the committees elected and appointed by the people, if in direct touch with the people, would afford the best system of control. He agreed there should be central bodies directing and diffusing information, but when it came to controlling, he said "No."

On Wednesday the representatives of the British Medical Association continued their evidence. The following gentlemen attended: Dr. Langdon-Down (Chairman, B.M.A., Lunacy Committee), Dr. J. W. Bone, Dr. C. O. Hawthorne, Mr. E. W. G. Masterman, Dr. C. Murrell, Sir J. Verrall, and Dr. C. C. Lord.

The Position of the Licensed House.

The Chairman said he assumed that the objection, in principle, to this kind of institution which was held by some was, that it might possibly cause conflict between duty and interest on the part of the management. Dr. Langdon-Down said he thought that was the basis of the theoretical objection, but in the main the reports concerning those houses were by no means adverse. Critics probably overlooked some other considerations, such as the desire of people to do a good thing and do it well, and the great stimulus of maintaining a good reputation. Answering the Chairman's remark as to suspicion based upon large profits made by these institutions, the witness said he knew nothing of the profits, but he did not think there was justification for the suggestion of exploitation.

The Chairman said that in the case of persons in these institutions who were possessed of some means, the suggestion had been that there might be a motive on the part of relatives to keep them under detention, and that those running the institution might have a pecuniary interest in the same direction. Dr. Langdon-Down rejoined that if a thing was wrong it should not exist at all, but if it was right to have such institutions the supply should meet the demand. If the safeguards were adequate, the Association thought this kind of institution should be encouraged, though that body did not wish to fortify a monopoly as such.

Functions of the Medical Superintendent.

Dr. Langdon-Down, in answer to the Chairman, said he did not think the Association had discussed the point whether the superintendent's medical work was interfered with by his administrative duties. In his own view, all the circumstances and environment of the patient were involved in his treatment. He thought the supreme authority in an asylum

ought to be its medical superintendent. Mr. Masterman gave some of his experiences as medical superintendent of a Poor-law hospital of 800 beds.

The Question of After-care.

The witness said he thought it would be well if those concerned in the working of mental institutions were to take a larger share in the after-care arrangements, especially by habitual communication with the patient's doctors after the patient had left the institution.

Sir Humphry Rolleston asked whether the Association would support any scheme for social service connected with mental hospitals whereby cases might be visited afterwards by friendly people who were virtually on the staff of the institution. Dr. Langdon-Down said he did not see any objection to this, which would be a reasonable extension of after-care. His Association, however, had not considered the matter. Dr. Murrell hoped that if such a recommendation was made by the Commission the patient's consent should be necessary, as the patient and his people might not wish to be followed to his home. He agreed that, with such a proviso, the medical value of such a scheme would be great.

Treatment of Mental Cases at General Hospitals.

Dr. Langdon-Down said he thought some provision for early treatment of mental disorder in clinics—admitting in-patients as well as out-patients—might with great advantage be linked up with teaching hospitals. And these would afford instruction in mental disorder for those entering the profession. He thought there was a tendency to encourage mental departments in general hospitals. The Chairman said he thought some form of constraint would be necessary in such a case, and this might be resented by the general hospital management. The witness pointed out that at Utrecht, in the psychiatric clinic there, though the patients came voluntarily, they were detainable. He wished to say, in emendation of a statement he made when last he attended before the Commission, that there were several institutions for the treatment of mental conditions which were not actual insanity; among them being Chichester House, Maudsley Hospital, and an Edinburgh institution. Maudsley Hospital was a model of what might be done.

Protection of the Doctor Certifying.

Dr. Hawthorne pointed out the differences existing between a lunacy certificate and a certificate given in, say, a case of small-pox. In the latter the doctor offered himself as one willing to certify and do what was necessary in the matter; but in the other case the doctor was very reluctant to certify a person as a lunatic, and he acted as a public servant, while in the other case he acted in the ordinary pursuit of his profession.

The Chairman rejoined that the doctor was a professional man who held himself out as one who was able to perform certain things in which he was skilled, and that was the criterion on which he must be judged. He thought it was asking much that the Commission would recommend the certifying doctor to have the same protection as a witness who gave oral testimony in court.

Sir Jenner Verrall suggested that there was a risk that doctors might not be doing their duty if their protection in this matter were not increased.

LIVERPOOL: NEW HOSPITAL FOR WOMEN.—Plans for a new building, estimated to cost £120,000, are now before the joint committees of the Hospital for Women, Shaw-street, and the Samaritan Hospital for Women, who are co-operating in the appeal for funds which is about to be launched. The new hospital, with the additional accommodation so urgently required, will provide the most modern facilities, and along with the new maternity hospital should place the treatment of diseases peculiar to women on a very high level.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

(Continued from p. 565.)

THE APPROVED SOCIETIES AND THE MONEY BENEFITS: CONTROLLER'S EVIDENCE—(continued).

How an Approved Society may be Formed.

(App. B. 1-6.) Any body of persons may make application to become an Approved Society, and on receiving approval may undertake the business of National Health Insurance. Two principal conditions must, however, be complied with. The society must not be carried on for profit, and its constitution must provide for its affairs being subject to the absolute control of its insured members.

Types of Societies.

Though there are many varieties of Approved Society, they fall into two main classes—namely, centralised societies (societies with central government and without branches) and societies with branches, commonly called "affiliated orders." These branches are variously termed lodges, courts, or tents. Each branch is self-governing in nearly every respect provided it avoids serious mismanagement, and it is a separate and independent financial unit. Employers' provident funds are in another class and may be approved, even though the employer is entitled to representation on the committee of the society.

There are many varieties of type and organisation which may affect the quality of administration, the expenditure on benefits, and the financial results of Approved Societies. For example, the field of operation may be limited to a village, town, country, or wider area. The class of members may be restricted in respect of sex, occupation, religion, or social habits. The origination of the society may also determine the membership according to the peculiar traditions of the parent body—trade union, dividing club, co-operative organisation, or some kind of federation.

Numbers and Membership.

(App. B. 32-38.) The number of Approved Societies in England at the end of 1923 was just under 1000, of which 28 were societies with branches. The number of branches was about 6100. These numbers (societies and branches) are about one-half of the numbers approved at the outset. As to the number of members in any society, the variations extend from eight societies each with less than 50 members, to two societies each with over a million members, and one with approximately two and a quarter million members. Two and a half per cent. of the societies contain no less than 76 per cent. of the total number of members. The reduction in the number of societies has been effected mainly by a transfer of their engagements. (App. B. 61.) This has come about because the intricate provisions of National Health Insurance proved too much for many small and inadequately equipped societies; they were unable to compete with the more effective organisations; the smallness of their membership handicapped them in regard to initial and continuing expenditure on administration; inability to check improper claims for benefit led to excessive expenditure and further weakened their financial resources; and they were largely unable to find competent officers to carry on the business. (Q. 610-615.) Administrative failure has, therefore, been responsible mainly for transfers of

* In previous articles the proceedings of the Commission were reported under the following headings: Introductory Note; The Scope of the Insurance Scheme (see THE LANCET, Jan. 31st, pp. 247-8); The Provision of Medical Benefit (Feb. 7th, pp. 301-3; Feb. 14th, pp. 355-6; Feb. 21st, pp. 403-5); Financial Provisions of the Act (Feb. 28th, pp. 454-7); Medical Certification and the Regional Medical Staff (March 7th, pp. 508-9); The Approved Societies and the Money Benefits (March 14th, pp. 564-5).

References to the official statement which has been issued as an appendix in four sections are given thus: Section A, para. 69, is shown as "App. A. 69," and references to the oral evidence thus—Q. 1369.

engagements. No difficulty has been experienced in finding societies willing to take over what might be regarded as derelict concerns.

A Unique System.

(Q. 511-512.) The Controller agreed that the system of administration by Approved Societies is unique in this country, being essentially different from the systems in force in regard to Public Health, Poor-law, and Unemployment Insurance. The Insurance Act did not, however, set up an entirely new machine. In addition to creating some new organisations it grafted a scheme of State Insurance on the existing arrangements of Friendly Societies, Trade Unions, &c.

(Q. 515, 516.) As a general rule the great majority of insured persons take little or no interest in the government of their society.

(Q. 514.) I suppose that, even with the provisions for self-government contained in the rules, the control of societies, especially the larger societies, must necessarily in practice fall very largely into the hands of the officers?—That is true of certain societies and especially of the larger ones, but it is not confined to the larger ones.

Further, although in theory subject to the absolute control of their members, societies are of necessity guided and supervised to a large extent by the Department.

Sir Walter Kinnear was asked :—

(Q. 519.) What do you consider the relative merits and defects of the large and the small centralised society as regards efficiency, cost of administration, financial stability, and so on?—That is a very large question, and I am very anxious not to appear to bias the minds of the Commission as regards any particular type of society. I should prefer that the members of the Commission were left with entirely open minds on the subject.

(Q. 520-528.) The present system whereby numerous societies operate in the same town undoubtedly adds to the cost of administration. The following figures were given for six towns taken at random: In the city of Liverpool, 488 societies have members; in Bolton, 285; in Brighton, 304; in Norwich, 213; in Reading, 245; in Tynemouth, 168.

The Defects of Segregation.

By the system of water-tight compartments members of particular trades may be worse off than under a universal system of insurance. The Controller said :—

(Q. 543.) I am bound to say that as a result of the amount of segregation which has taken place, the problem of a certain number of the societies, composed largely of persons belonging to industries where the standard of health is not particularly high, is becoming rather a serious one.

Valuation.

(App. B. 153.) Societies and branches are required to be valued every five years by a valuer appointed by the Treasury. The process of valuation consists of a measurement of the value at the valuation date of future benefits and of future receipts from contributions, &c.

(App. B. 159, 160.) The accumulated funds of societies at the date of the last valuation were about £120,000,000. The valuation showed a net surplus of £17,000,000. (App. B. 178-9.) This amount must be distinguished from the disposable surplus, which it is the valuer's responsibility to determine. This amounted to £9,000,000, the balance of £8,000,000 forming a reserve which the valuers considered it important to maintain.

(Q. 796-7.) On the first valuation were the financial results much better than were expected; . . . will you explain broadly the reasons for this?—The chief contributory causes of the large surplus were, first of all, a low claims experience, especially during the period of the war; a high interest yield on investments; a high average of contributions received by societies during the period; and, as regards men's societies, a high rate of mortality among men during the war, which had the result of reducing the liabilities of societies and releasing substantial reserves.

The Controller said that the first valuation covered such an exceptional period that it would not be safe to draw any definite inference from it.

(Q. 803.) Do you expect the results of the valuation now proceeding to be as favourable as those of the 1918 valuation? Can you give us any approximate estimate of the expected surplus as compared with the 17 millions of the last one?—I understand that the results of the valuation now proceeding promise to be very satisfactory. But the Department has as yet received no reports from the Treasury valuers, and until we do so it is impossible for me to give you any figures.

(Note.—Since this evidence was given it has transpired that the new valuation is producing results even more favourable than the 1918 valuation.)

Sickness Experience.

(Q. 831-2.) The sickness experience on which the Act was based was the Manchester Unity experience of 1893-7. Partly because this was not up to date, sickness experience proved to be much less than expectation. The general view is that the standard of health of the people has greatly improved.

(App. B. 169.) As most societies do not impose any occupational restriction on their members, and even trade-unions and other similar Approved Societies are not always limited to members following exclusively any particular occupation, the records of societies cannot indicate with any precision, if at all, the sickness or invalidity experience according to occupation.

Additional Benefits.

(App. B. 180.) The disposable surplus may be distributed by societies in the form of prescribed additional benefits, of which there is a pretty wide range. They consist chiefly of increases in the normal cash benefits, in payment of the whole or part of the cost of dental or optical treatment, maintenance and treatment in hospitals or convalescent homes, medical and surgical appliances, provision of nurses, and other benefits of the same character (conveniently described as "non-cash" or "treatment" benefits).

(App. B. 185-190.) Of the £9,000,000 disposable surplus the proportion belonging to societies with head offices in England is £8,000,000. It is interesting to note that of this amount nearly three-quarters was applied in additional cash benefits, and one-quarter only in non-cash benefits. The societies had almost a complete discretion as to the way in which they should apply their disposable surpluses, and there appears to have been a general plumping for cash benefits, and, on the other hand, a considerable absence of uniformity both in regard to the scope of particular non-cash benefits, and as to the proportion of cost borne by the societies.

(Q. 880.) The benefits under the first valuation have been to some extent experimental, and there has been a danger of societies adopting a benefit without devoting enough money to it. The Controller said :—

We are very anxious that societies should not be allowed to adopt additional benefits for window-dressing purposes; that they should not be able to advertise that they are giving additional benefits for which the sum of money allotted is not sufficient to meet the normal application.

(Q. 883.) In connexion with the new valuation results, the Department will probably insist in regard, e.g., to dental benefit, on a uniform definition so as to avoid friction and misunderstanding.

Distribution of Insured Persons amongst Societies.

From the tables accompanying the Controller's evidence one very short extract follows. The membership of societies of different types for the whole of Great Britain was for the year 1920 :—

Type of society.	No. of members and percentage of total.
Friendly Societies with Branches . . .	3,290,000 (22·7)
Friendly Societies (centralised) . . .	3,451,000 (23·8)
Trade Unions . . .	1,449,000 (9·9)
Employers' Provident Funds . . .	120,970 (0·8)
Industrial and Collecting Societies . . .	6,211,000 (42·8)
Total membership . . .	14,521,970

It will be seen that nearly one-half of the insured persons are members of the Industrial and Collecting Societies. Of the total membership of all the societies about 9½ million are men and about 5 million are women.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow University.

Medical Benefactions.—The late Dr. John Hall, of St. John's Wood, London, who died in 1909, left the reversion of one half of his residuary estate to the University of Glasgow for the endowment of certain "tutorial fellowships" in medicine, surgery, and midwifery, and for the better equipment of practical teaching in these departments. The reversion has now accrued through the recent death of Miss Hall, the testator's sister, who has added half her own estate for the increase of her brother's benefaction. The whole endowment will amount to about £50,000; but some months must elapse before it is realised, and a scheme is formulated for its application. In view of the large clinical schools connected with the University at the Royal, Western, Maternity, Sick Children's, and other hospitals in Glasgow, the foundation will be a notable addition to the medical resources of the University.

The Gifford Lectures.—Dr. John Scott Haldane, F.R.S., Fellow of New College, Oxford, has been appointed Gifford Lecturer at Glasgow for 1926–27.

Zoology and the Medical Curriculum.

Prof. J. Graham Kerr made some interesting general remarks on this subject at a recent meeting of the Glasgow Royal Medico-Chirurgical Society, with Prof. Archibald Young, the President, in the chair. It was now generally recognised, he said, that zoology was one of the important basic sciences in the training for medicine. Perhaps the most important object of the zoological course was the training in biological method—which was the method used later on in the general work of the practitioner. It was not the method of the "exact" sciences, consisting mainly of measurement and calculation, but rather the method used in early childhood when by far the greater part of the mental development took place. In ordinary school training this method was excised and in its place was put training in the gulping down without question of information served out by the teacher. The result was apt to be disastrous to the development of the powers of observation and reasoning upon observation, and to undo this harm and to develop further these powers was the greatest function of the introductory zoological part of the curriculum. Emphasis was laid upon the special importance of drawing as a means of developing the scope of observation. The part played by the course in zoology in leading up to courses in anatomy, physiology, and pathology was emphasised, and Prof. Kerr concluded by accentuating the importance of turning out the fully qualified practitioner at the end of his curriculum as a naturalist who would view the problems before him with the eye of the naturalist. Many of the greatest triumphs of medicine in the past—the solution of such problems as inflammation, malaria, yellow fever—had been reached by tackling particular problems as problems in natural history, and who could doubt that the same would be the case in the future?

The Expectation of Life in Glasgow.

At the closing ceremony of the winter session of Anderson's College of Medicine, Glasgow, on Thursday, March 12th, Captain Walter Elliot, M.P., Parliamentary Secretary to the Scottish Board of Health, gave an address on the prevention of infectious diseases and the direction in which we may look for advance in this field of public health. During the past century, he said, preventive medicine had achieved some of the greatest triumphs that any department of science had ever been able to place to its credit. The problems it had had to face and solve were created by the great development of urban life. In illustration of this he mentioned that between

1801 and 1851 the population of Glasgow had increased by 346 per cent.—that is to say, from a population of 77,000 to one of 345,000. Another 650,000 came in the second half of the century. The first quarter of a million was accompanied by a tremendous increase in the death-rate, but the last 600,000 was accompanied by an equally striking decrease. In the years 1821–27 the expectation of life of a 10-year old boy in Glasgow was 42 years, while from 1832–34 it had fallen to 37 years. It was not until 1881–90 that it came up above what it had been in the 'twenties of the century, and it then had risen to 44 years. At the present time the high-water mark was 50½ years. With regard to an elderly man the Biblical three score and ten still ruled, but the conservation of life applied to many who formerly died off in early manhood or womanhood. Even as late as 1870, of 1000 boys in Glasgow, half of them were dead by the age of 25, while of the same number to-day half of them were still alive at the age of 58. Put in another way, the present population of Glasgow would live 20 million years more than a similar number half a century ago, and the increase of the life capital of Glasgow was estimated at 1000 millions sterling. That, said Dr. Elliot, was a very great achievement for preventive medicine, not only in the humanitarian but in the economic field.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Royal College of Surgeons in Ireland.

THE Charter Day dinner of the Royal College of Surgeons in Ireland was held on Saturday, March 14th, in the hall of the College, when Mr. R. C. B. Maunsell, President, presided over a company of 100 Fellows and their guests. Lord Glenavy, Chairman of the Senate, was principal guest, and responded to the toast of "The Governor-General and Prosperity to Ireland," the Governor-General himself being unable to be present. Among other guests who spoke were the Provost of Trinity College and Mr. Justice FitzGibbon.

Honorary Degrees at Dublin University.

The Senate of Dublin University met last Saturday to consider graces for certain honorary degrees. Among those approved by the Senate were graces to confer the honorary degree of D.Sc. on Sir Frederick G. Hopkins, of Cambridge, and the degree of M.Ch. on the famous Americans Dr. G. W. Crile and Dr. Charles Mayo.

Medical Men Elected to the Dail.

His many friends have welcomed the return of Mr. T. Hennessy, F.R.C.S.I., as deputy for the South Dublin City constituency, by an unexpectedly large majority. He polled some 5000 votes more than the combined poll of his two opponents. Mr. Hennessy has been honorary secretary of the Irish Medical Committees for many years, and his presence in Parliament should be of service to the profession. In a bye-election in Cavan last week Dr. O'Reilly was elected.

Mercer's Hospital.

Every year one or more of the Dublin hospitals has to make its special appeal for funds to enable it to carry on its work. Last year it was Sir Patrick Dun's Hospital and the Royal City of Dublin Hospital. This year Mercer's Hospital is before the public. Last week a meeting of its friends was held in the hospital to make its needs known. The chair was occupied by Lord Glenavy, a governor of the hospital, and the Governor-General was present. It was stated that recently a new system of heating had been installed, and a new X ray apparatus had been purchased. These changes had not been undertaken until they were necessary, and further changes would soon compel the governors to further expenditure.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Experimental Syphilis.

THE Institut Pasteur of Paris has extended a welcome to two Argentine scientists, Drs. Jaurégui and Lancelotti, to enable them to continue the experimental researches on syphilis in llamas at which they have been working for the past 12 years. Arrangements have been made for the transport from Bolivia to Paris of a number of llamas, some of them vaccinated and others entirely untouched. The two doctors have discovered that syphilis develops in the llama on the same lines as in man, but with much greater rapidity, and completes its course at the end of three weeks by causing serious nervous symptoms which have a fatal issue in a few days. A culture of the specific organism has been prepared in human serum under anaerobic conditions, and after gradual attenuation by heat this culture has been used to vaccinate the experimental animal. From the animal thus immunised it has been possible to prepare a serum which cures the primary and secondary stages of syphilis in the llama. The cure is complete in a few weeks, and is verified by the fact that at the end of four months the animal is again liable to contract the disease. Although at present vaccination has produced temporary effect only and must be repeated after a time, nevertheless the serum does effect a definite cure. Animals treated in this way over seven years ago have remained absolutely free of infection. Encouraging results have already been obtained in human subjects, but the proof of time is still necessary, and the experiments require further rigid control. The existence of syphilis in llamas is of interest in relation to the old legend that the disease was first brought to Europe by the discoverers of the Americas.

The Function of the Larynx.

Dr. Marage, of Paris, demonstrated recently to the Academy of Medicine the results of experiments he conducted to determine the precise rôle of the larynx and the mouth in the formation of vowel-sounds. In his first experiment he occluded the mouth by filling it with the substance which dentists use to take impressions of the buccal cavity; under these conditions he found that the subject could pronounce the five fundamental vowel sounds perfectly. In his second experiment he found that if the larynx of a chloroformed dog were removed, the organ remained alive for a few minutes. If the various muscles were made to contract by the application of an electric current, and if at the same time a blast of hot moist air were passed through the larynx, the noise of barking was produced just as if the animal were alive. The whole organ changed its shape at each note. Therefore the larynx alone, apart from the mouth, can produce these vibrations. Finally, in order to investigate the actual working of the larynx, he obtained a cinematographic picture of the vocal cords. This film enabled him to demonstrate the vocal cords very clearly to his audience, and further permitted a detailed study of the vibrations of the cords, their changes in length and breadth, and the variations in the shape of the larynx during phonation.

Memorials to Two Surgeons of Lyons.

Two monuments were unveiled in the large amphitheatre of the Faculty of Medicine of Lyons on Sunday, March 8th, in memory of two great French surgeons who had lived and worked in Lyons. The one, Poncet, was for 30 years a distinguished Lyons surgeon; it is to him that we owe the conception of tuberculous rheumatism, the existence of which he supported energetically and persuasively, particularly before the Academy of Medicine. The other, Jaboulay, was his pupil, a skilful operator who did important work in the surgery of the nervous system. Among the speech-makers at the ceremony were Prof.

Lépine, Dean of the Faculty of Medicine of Lyons, Dr. Jean Louis Faure, of Paris, in the name of the Academy of Medicine and of the Société Nationale de Chirurgie, and Dr. Ierich, of Strasburg, one of Poncet's former pupils.

The Danger of Radio-active Substances.

The Academy of Medicine has had under consideration the danger involved in the handling and transport of radio-active substances, and as a result recently made the following recommendations: (1) That the industrial preparation, handling, or transport of radio-active substances be classified among the noxious trades, not as regards the neighbourhood of the factories, but from the point of view of the workers; and (2) that strict supervision of the hygienic conditions obtaining in such establishments be instituted, together with suitable rules and regulations, on the findings of a scientific and technical commission.

RUTHERFORD MORISON TESTIMONIAL.

THE following is the second subscription list for the Rutherford Morison Testimonial Fund, the inauguration of which was announced in THE LANCET of Jan. 17th, p. 146:—

£25.—Mr. G. W. Richardson, Keswick; Mr. S. S. Whillis, Newcastle.

£10 10s.—Drs. Baigent and Hutchinson, Northallerton; Dr. J. J. Campbell, Newcastle; Dr. J. Charles, Stanley; Mr. J. Clay, Newcastle; Dr. W. S. Dickie, Middlesbrough; Dr. A. Duke, Newcastle; Dr. C. W. M. Hope, London; Lieut.-Colonel A. H. Proctor, Darjeeling; Dr. Fred. Proud, Newcastle; Mr. S. Raw, Sunderland; Dr. W. L. Ruxton, Newcastle.

£8.—Dr. G. W. Pailthorpe, London.

£5 5s.—Dr. H. H. Aitchison, Wallsend; Dr. J. Anderson, Seaton Delaval; Dr. W. D. Arnison, Newcastle; Dr. V. F. Badcock, Cornhill-on-Tweed; Dr. J. Bannerman, Stanhope; Mr. James Berry, London; Dr. H. S. G. Boswell, Hartlepool; Dr. C. E. L. Burman, Ladysmith, Natal; Dr. Mabel Campbell, Newcastle; Dr. W. S. Campbell, Sidmouth; Prof. Sir David Drummond, Beal; Mr. Horsley Drummond, Newcastle; Dr. H. A. Fielden, Torquay; Dr. Garson, Sacriston; Dr. J. C. Hamilton, Sunderland; Mr. J. Hamilton-Barclay, Newcastle; Mr. N. Hodgson, Newcastle; Dr. J. A. McLeod, Alnwick; Dr. S. D. Metcalfe, Newcastle; Dr. H. B. Ord, South Shields; Dr. H. W. T. Russell, Trimdon Station; Dr. T. Russell, Trimdon Grange; Dr. W. Seymour, Newcastle; Dr. J. S. Taylor, Vryheid, Natal; Dr. R. Walker, Wooler; Dr. R. J. Weidner, North Shields; Dr. J. Whyte, South Shields; Surg.-Comdr. F. G. Wilson, R.N.

£5.—Dr. E. Davison-Smith, Whickham; Dr. Ruth Nicholson, Liverpool; Mr. A. S. Percival, Newcastle (second donation); Dr. Olive Wilson, Newcastle.

£3 3s.—Dr. N. R. Beattie, Walker Gate; Dr. E. C. Braithwaite, Warri, Nigeria; Dr. H. P. Bennett, Newcastle; Dr. Craven, Bensham; Dr. A. J. Dale, Worcester; Dr. W. H. Dickinson, Newcastle; Dr. A. Fairlie, Blyth; Dr. J. Gilmour, Newcastle; Dr. Harland, South Shields; Dr. S. McCoull, Wylam; Dr. Angus Martin, North Shields; Dr. E. Farquhar Murray, Newcastle; Dr. G. R. Murray, Manchester; Dr. G. R. Newsome, Manchester; Dr. J. C. Norman, Hebburn; Dr. Freda Ramsay, Beckenham; Surg.-Comdr. B. Robson, H.M.S. *Princess Margaret*; Dr. H. L. Rutter, Newcastle; Dr. W. Stimpson, Newcastle; Dr. J. Swanberg, London; Mr. G. Gordon Taylor, London.

£2 2s.—Dr. T. Aitchison, Willington Quay; Dr. M. A. Archdale, Ryhope; Dr. T. H. Bates, Newcastle; Dr. Frank Beaton, Ashington; Drs. W. A. and E. G. Benson, Stanley; Dr. J. S. Brogdon, Hartlepool; Dr. J. R. Burn, Easingwold; Dr. A. Campbell, Heaton; Lieut.-Colonel T. T. Coates, Woolwich; Dr. H. Crichton, South Shields; Dr. H. I. Daggett, Boroughbridge; Dr. T. Dixon, Earsdon; Captain H. H. Elliott, Bombay; Dr. Anne Fairweather, Birmingham; Dr. Gardner, Darlington; Mr. W. A. Hewitson, Newcastle; Dr. W. Holmes, Ponteland; Dr. M. Jacobs, Hull; Dr. Lillie Johnson, Jarrow; Dr. Leishman, Barnard Castle; Dr. J. Macfadyen, Newcastle; Dr. D. R. MacGregor, Wallsend; Dr. McCullagh, Bishop Auckland; Dr. T. W. Maddison, London; Dr. W. Martin, Newcastle; Dr. D. M. Millar, Felling; Dr. I. M. Pirrie, Maldon; Mrs. E. Pirrie, Maldon; Mr. F. W. Ramsay, Bournemouth; Dr. Margaret Ranken, Sunderland; Dr. N. R. Rawson, Whitley Bay; Dr. D. R. Roberts, New Tredegar; Dr. R. Sanderson, Maryport; Dr. A. F. Bernard Shaw, Newcastle; Dr. Sparks, Whitley Bay; Dr. F. S. Walker, Newcastle; Dr. N. B. Walley, Dudley; Mr. C. Hamilton Whiteford, Plymouth; Dr. G. S. Woodman, Baghdad.

£2.—Dr. S. Louise Rook, Bradford; Dr. L. H. Walker, Dinnington; Dr. Edith S. Williamson, Newcastle.

£1 1s.—Dr. E. C. Abraham, Wolston; Dr. A. Angus, Tyne-mouth; Dr. F. Barrow, Rothbury; Dr. J. L. Blandford, Henwick; Dr. H. C. Broadhurst, Hebburn; Surg.-Comdr. H. M. Braithwaite, H.M.S. *Valiant*; Dr. M. Brennan, Gateshead; Dr. J. F. Bridge, Leamington Spa; Dr. Brown, Newton Abbot; Dr. J. Ferens Colman, London; Dr. Corben, Cheam; Dr. Hedvig K. Cyriax, Nuneaton; Dr. H. G. Dodd, Hove;

Dr. Dougall, Gateshead; Dr. W. A. Elliott, Southampton; Dr. A. L. Fairlie, Cowpen; Dr. C. F. Fairlie, Blyth; Dr. H. E. Fellowes, Newcastle; Dr. W. Gibbons, Gateshead; Dr. Gilbert, Gateshead; Dr. J. E. Goffton, Paignton; Dr. W. Graham, Linthorpe; Dr. John Gray, Stanhope; Dr. Barbara N. Grinling, Newcastle; Dr. F. W. Gunn, Ashington; Dr. Helen Gurney, Newcastle; Dr. W. Hall, Sacriston; Dr. Norah Hamilton, Sunderland; Dr. A. S. Hedley, Rothbury; Dr. L. F. Hemmans, Lewisham; Dr. C. J. Henderson, Lancaster; Mr. J. P. Higham, Middlesbrough; Dr. R. S. Hindmarch, Gateshead; Dr. M. Hunter, Ferryhill; Dr. R. Hunter, Brampton; Dr. G. E. Hyden, Blackhill; Dr. J. A. Kendall, Brixton; Dr. H. Kerr, Newcastle; Dr. H. H. Laurence, Shotton Colliery; Dr. F. S. Leech, Gateshead; Dr. H. L. de Legh, Shincliffe; Dr. D. J. Lewis, Machynlleth; Dr. F. J. Lidderdale, Cheltenham; Dr. W. G. Lidderdale, Cheltenham; Major W. E. C. Lunn, Netley; Dr. G. McCoull, Prudhoe; Dr. J. R. McCurdie, Middlesbrough; Dr. McElroy, Blackhill; Dr. Mackenzie, Consett; Dr. H. E. Mather, Pemberton; Dr. N. A. Martin, Tunbridge Wells; Dr. F. W. Melvin, Oswestry; Dr. Jean M. Morton, Nottingham; Dr. S. E. Murray, Leicester; Dr. H. Newsome, Pill; Dr. D. F. O'Kelley, Boldon Colliery; Drs. MacRae and Raine, Corbridge; Dr. S. Phillips-Bedson, London; Dr. T. Brice Poole, Westcliff-on-Sea; Dr. Smallwood, Gateshead; Dr. A. Smith, Swallow; Dr. J. L. Spiers, Gateshead; Major T. W. Stallybrass, Hounslow; Dr. Russell Steele, London; Dr. J. B. Tighe, Stannington; Dr. Dorothea M. Tudor, Leamington Spa; Dr. W. A. Tweddle, Newcastle; Dr. W. Vincent, Sheffield; Dr. Olivia N. Walker, Plymouth; Dr. G. W. Weir, South Shields; Dr. J. Whillis, Gosforth; Dr. A. F. Wilkin, Yarm-on-Tees; Dr. H. A. Wilson, Newcastle; Dr. W. Q. Wood, Edinburgh.

41.—Dr. Soliman, Birmingham.
10s. 6d.—Dr. Christina Barrowman, Newcastle; Dr. R. E. Brown, Willington; Dr. Craig, Dudley; Dr. H. W. Eyres, Richmond; Dr. T. M. Kimpster, Gateshead; Dr. N. C. Leinard, Bristol; Dr. G. H. Lowe, Middlesbrough; Dr. H. H. Maidlow, Ilminster; Dr. Moore, Gateshead; Dr. H. Munro, Nettlesworth; Dr. E. R. Pantcheva, Buckhurst Hill; Dr. M. Scoresby-Jackson, London; Dr. Weldon Watts, Newcastle.

10s.—Dr. Florence B. Lambert, London; Dr. J. W. Sandhoe, Broad Clyst.

5s.—C. F. D. H.
Subscriptions promised, but amounts not specified.—Dr. Modlin, Sunderland; Dr. Norris, Gateshead; Dr. W. Smith, Gateshead.

The sum of £1143 7s. has been subscribed to date. The Committee has decided to close the Fund on March 31st, until which date subscriptions may be sent to the hon. secretary and treasurer, Mr. R. J. Willan, at 9, Kensington-terrace, Newcastle-upon-Tyne.

The Services.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. (D) G. W. E. Holloway to be Surg. Lt.-Comdr. (D).

ROYAL ARMY MEDICAL CORPS.

Maj. and Bt. Lt.-Col. C. W. Holden to be Lt.-Col., vice Lt.-Col. J. Dorgan, to ret'd. pay.

Capt. T. V. Oldham retires, receiving a gratuity, and is granted the rank of Maj.

The undermentioned Capt. retire: H. G. Dresing, receiving a gratuity; J. B. Williamson, on account of ill-health.

SUPPLEMENTARY RESERVE OF OFFICERS.

H. L. Oldershaw to be Lt.

TERRITORIAL ARMY.

2nd Lt. K. V. Milburn (late R.F.A., T.F.) to be Lt.

ROYAL AIR FORCE.

Flight Lt. A. F. Rook is promoted to the rank of Squadron Leader.

Group-Capt. N. J. Roche is placed on half-pay, Scale A.

INDIAN MEDICAL SERVICE.

G. J. Smith to be Capt.

C. A. Bozman, A. Rosenbloom, M. P. Conroy, W. Scott, S. C. H. Worseldine to be Lts.

The King has approved the retirement of Lt.-Col. A. E. Walter and of Maj. J. H. Horne (on account of ill-health).

MENTIONED IN DESPATCHES.

The names of the undermentioned officers of the Indian Medical Service have been brought to notice for distinguished service during the operations in Waziristan, April 21st, 1923, to March 31st, 1924: Capt. T. R. Birmani, C. M. Ganapathy, D. V. O'Malley, M. V. Pathak, B. Prasad, and R. V. Rau.

MEDICINE AND THE LAW.

HARNETT v. BOND AND ADAM.

THERE has been furnished in these columns a very full account of this important case. It will be remembered that an original judgment awarded immense damages against Dr. C. H. Bond and Dr. G. H. Adam for the alleged wrongful detention of Mr. W. S. Harnett in a lunatic asylum. The trial lasted 16 days and we published a full summary of the evidence, speeches, and summing up in THE LANCET of March 8th, 1924. On appeal the judgment was set aside, and in THE LANCET of May 24th, 1924, will be found the considered judgments delivered in the case by Lords Justice Bankes, Warrington, and Scrutton. This week the House of Lords rejected the appeal of Mr. Harnett against the reversal by the Court of Appeal, while the importance of the case is recognised by the fact that the Lord Chancellor has stated that time would be taken to put their Lordships' reasons in writing.

THE LONDON SOCIETY OF APOTHECARIES RECOVER A PENALTY.

In the county court at Nuneaton the London Society of Apothecaries recently obtained judgment for £20 and costs against Mrs. Ashton, the Coton Drug Stores, Nuneaton. The defendant, having no qualification to act as an apothecary, had treated a child suffering from small-pox as if for a cold, with the result, it was alleged, that other persons had come in contact with the patient and had been infected. The sum of £20 thus recovered is the penalty prescribed by Section 20 of the Apothecaries Act of 1815, authority to sue for which is given by that Act to "The Master, Wardens and Society of the Art and Mystery of Apothecaries of the City of London." The penalty is not often sued for by the Society, presumably because practising as an apothecary without having the Society's certificate is an offence not easy to detect and prove without an elaborate system for that purpose. It will be observed that the proceedings in these cases are taken in a civil court and are not "prosecutions."

A notice of appeal has been entered.

ACTION ARISING OUT OF BARBER'S ITCH.

The probable origin of a case of tinea sycosis, or barber's itch, was recently the subject of conflicting medical evidence in the Court of Appeal. Barber's itch is a disease of the bearded parts of the face and neck, caused by *Trichophyton tonsurans* and marked by the formation of reddish concentric patches covered with dry fragile hairs and yellow scales or pustules. The appellant was a hairdresser, against whom judgment had been obtained in the Birkenhead county court for £19 15s., the plaintiff's case being that he had been shaved on a certain Saturday in the appellant's shop, and on the next day had developed a rash which had been diagnosed later as "barber's itch." It was submitted on behalf of the barber that there was no evidence of negligence on his part, and none that the disease could not be contracted otherwise than by shaving; and that the evidence was consistent with the disease having been contracted elsewhere than in the barber's shop. The medical evidence called had ascribed the disease to the shaving, but medical evidence for the defence had contradicted this. Lord Justice Bankes, in giving judgment, said that there could be no question that if the plaintiff had become infected through being shaved it must be due to negligence on the defendant's part in not taking proper precautions. There was a conflict of evidence as to whether the disease contracted had in fact been barber's itch, but the county court judge was entitled to come to the conclusion at which he had arrived. There was evidence as to the defendant not being shaved daily, but going to the defendant's shop of a Saturday night, and evidence of the state of his skin on the evening in question. Upon such evidence it was open to the judge to find that the plaintiff had contracted barber's itch as claimed by him. The appeal was therefore dismissed.

THE CROWBOROUGH TRAGEDY.

The long trial of John Norman Thorne for the murder of Elsie Cameron at Crowborough on Dec. 5th, 1924, came to an end on Monday night last with the verdict of Guilty. The verdict was determined by the general circumstances of the case, but at one point the medico-legal evidence was of great significance, and not unanimous. Full consideration was given to detailed testimony in opposition to Sir Bernard Spilsbury's reasoned view, expressed for the Crown, that the bruises on the corpse were caused shortly before death and that there were no discoverable signs of hanging. The jury set aside the defence of an attempt at suicide by hanging. It is understood that an appeal is to be entered.

THE BATEMAN APPEAL.

As already explained in THE LANCET, it has been felt that material assistance ought to be offered to Dr. Bateman to meet the legal expenses of his recent successful appeal against conviction and to make good the deficiency in his professional income. Accordingly, the Bateman Fund has been opened and lists of contributions have appeared in recent issues. We have received additional contributions as follows:—

	£	s.	d.
Amount already received and acknowledged	353	14	6
Dr. Henry Russell Andrews	5	5	0
J. T. R.	5	5	0
Mr. Tyrrell Gray	5	0	0
Dr. A. Graham-Stewart	2	2	0
Dr. Joseph A. Arkwright	1	1	0
Dr. T. C. Blackwell	1	1	0
Dr. J. Newman Darling	1	1	0
Dr. J. C. Jefferson	1	1	0
Dr. W. Gifford Nash	1	1	0
Dr. Wilson Tyson	1	1	0
Dr. J. H. Stephen	1	0	0
Dr. Montague Cutcliffe	0	10	6

Remittances should be forwarded to the Manager of THE LANCET, 423, Strand, W.C.2, and made payable to the "Bateman Fund Account."

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 7TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 122; scarlet fever, 1606; diphtheria, 941; enteric fever, 41; pneumonia, 1441; puerperal fever, 39; cerebro-spinal fever, 6; acute poliomyelitis, 4; encephalitis lethargica, 61; continued fever, 1; dysentery, 8; ophthalmia neonatorum, 121. There were no cases of cholera, plague, or typhus fever notified during the week. The number of small-pox cases showed a decrease of 19 from the number for the preceding week. Thirty-one cases were notified from Derbyshire, 21 from Northumberland (Ashington, 13), 6 from Notts, and 45 from Yorks, North Riding (Middlesbrough C.B., 39).

Deaths.—In the aggregate of great towns, including London, there was 1 death from enteric fever, 111 from measles, 11 from scarlet fever, 108 from whooping-cough, 40 from diphtheria, and 361 from influenza, as compared with 346, 352, 354, and 291 in the four preceding weeks. In London itself the deaths from influenza numbered 59, from whooping-cough 30, and from diphtheria 16.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The twenty-first meeting of the Commission was held at the Home Office, Whitehall, on March 12th, Sir Andrew Duncan in the chair. The National Federation of Rural Approved Societies, represented by Mr. W. Wood and Mr. W. Hyde, gave evidence on the position and experience of rural societies under the insurance scheme. Evidence relating to a particular society, the Scottish Rural Workers' Society, was given by Mr. James Falconer and Mr. Wood. Thereafter Sir Norman Hill was examined on the working of the Seamen's National Insurance Society. The Commission announce that proof copies of the oral evidence and the relative statements submitted at the meeting of Feb. 26th are now on sale at H.M. Stationery Office.

Correspondence.

"Audi alteram partem."

THE BATEMAN FUND.

To the Editor of THE LANCET.

SIR,—In enclosing my contribution towards the Bateman Fund, I should like to say that I hope this appeal will meet with a very hearty response. If every member of the profession would send even a very small contribution, I do not doubt but that this would be of vast material help to Dr. Bateman—though nothing in the way of money can ever hope to recompense him for what he has had to go through. But it will show him that he has the help and the practical sympathy of his professional brethren—surely of some solace. I think the Proprietors of THE LANCET are to be highly congratulated on their generous contribution.

We are all a good deal at the mercy of patients, and even the most careful and conscientious medical man never knows the moment when he may be at the mercy of a jury utterly ignorant and incapable of judging a highly technical matter. It takes but little imagination to conjure up what Dr. Bateman has had to go through, and what the cost to him both in health and in practice must be.

I am, Sir, yours faithfully,
Margate, March 13th, 1925. A. GRAHAM-STEWART.

To the Editor of THE LANCET.

SIR,—I have great pleasure in forwarding you cheque as a small contribution to the Bateman Fund. I trust you will be able to raise a large sum for this very deserving object.

I am, Sir, yours faithfully,
Aberdeen, March 15th, 1925. JOHN H. STEPHEN.

HEALTH STATISTICS OF THE MERCANTILE MARINE.

To the Editor of THE LANCET.

SIR,—It is hoped that the timely leading article upon this subject which appeared in THE LANCET of March 14th will arouse the conscience of the Board of Trade as to its duty towards the men of this fine service.

In this connexion I would ask your permission to direct attention to one aspect of the health problem of the sailor which profoundly affects the general community. It is that of venereal diseases. The Merchant Shipping Act of 1916 provided that the expense of the treatment of the sick sailor should be borne by the owners of the vessel upon which he was employed; but it excluded from this benefit the seaman suffering from venereal disease and made no provision for him. While the Civil and the Service sections of the population have special V.D. schemes provided for them, the merchant seaman is practically neglected. From the nature of his occupation, the site of his labours, and the general conditions under which he exists, very special measures are required for dealing with him when he is suffering from venereal disease. At the present time there exists a large floating population of venereally infected mariners; these are sowing, and others are reaping, syphilis and gonorrhoea in every port in the world. I have the highest admiration for the merchant seaman, and I can claim an intimate knowledge of his life, his health, and his temptations owing to the fact of having at one time served as an ordinary seaman on ocean-going "tramps." It is a calling which is heavily infected with venereal disease—and indeed it is little wonder. The drink-shops and the harlots of "sailor-town" are always upon the look-out for the seaman with wages to spend. His arduous and cheerless life at sea, with its perils and its separation from home-life, make him, when

ashore, very susceptible to influences which part him from his money, and too frequently fasten upon him syphilis or gonorrhœa.

A few years ago Prof. E. W. Hope, M.O.H. for the City and Port of Liverpool, showed that 37 per cent. of the total patients attending the V.D. centre at Liverpool Royal Infirmary were seafarers, and that 15 per cent. of those were of foreign nationality. One would appeal for more adequate measures for dealing with these men. It is by no means sufficient to provide a treatment centre remote from the docks and expect to attract the men to it on week-days. There should be a treatment centre actually at the docks, and exclusively for the use of sailors. This should be open every night and all day on Sunday. At this place prophylactic treatment would be available. When a ship arrives in dock, a notice should be posted in the fore-castle giving information as to the position of the treatment centre and the facilities it affords. From the nature of the calling of these men, the matter is really an international one and might well receive the attention of the League of Nations or the International League of Red Cross Societies. Only thus will the seaman be able to secure some approximation to continuity of treatment.

From an international public health point of view a V.D. examination of men joining a ship is of high importance. At these treatment centres this might be done, and inquiries made as to recent exposure to infection. If there had been such exposure, prophylaxis would be administered and a certificate to that effect would be attached to the man's papers. This would be destroyed at the end of the syphilis incubation period. If the man denied exposure, and in consequence did not receive preventive treatment and subsequently developed venereal disease, he would then be liable to stoppage of pay during his illness.—I am, Sir, yours faithfully,

Manchester, March 16th, 1925.

E. T. BURKE.

OCULAR COMPLICATIONS IN GENERAL ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—In an article in the *British Journal of Anaesthesia* for October, 1923, entitled *The Value of the Reflex Basis in the Interpretation of Phenomena during General Anæsthesia*, I pointed out that inflammation of the conjunctiva could occur, apart from the introduction of anæsthetic liquid into the eye. The essential point referred to is, that mere exposure to air of such a delicate membrane as the conjunctiva is sufficient to produce inflammation if the protective mechanism—the blinking reflex—is removed. This reflex normally occurs two to three times per minute and prevents desiccation and deposition of minute particles by constant swilling with lacrymal secretion. If the administration of a general anæsthetic be prolonged, and the corneal reflex and lacrymal secretion abolished, the eyelids under these circumstances remain partially open, and the protective reflex being abolished, redness and inflammation of the conjunctiva may supervene. Elderly patients are especially prone to exhibit widely open eyes during general anæsthesia owing to the loss of tone of the orbicularis palpebrarum muscle, but any prolonged deep anæsthesia, especially if associated with shock, is apt to be associated with widely open lids, thus favouring the production of the condition. A series of observations were made in the case of a hospital resident whose anæsthetic cases showed an excessive proportion of inflamed eyes. No anæsthetic was allowed to get near the eyes, he was not allowed to take an eye reflex, the face pads were frequently changed, and yet at the end of the operation the conjunctiva was dry and showed vivid red injection. The complication may be avoided by frequent approximation of the lids and by rolling the upper lid over the globe of the eye from time to time so as to distribute the residual

secretion, or failing this by putting a little warm saline into the eye. If this be done the conjunctiva will be perfectly pale at the end of the operation. Another cause of inflamed eyes which is not generally recognised is the presence of vomit, with dissolved anæsthetic, on the patient's pillow and this may get into the patient's eye. Immediate cleansing with warm saline will correct any ill effect.

An analogous condition used to be seen in the operation for removal of the Gasserian ganglion. If the ganglion were completely removed destructive changes were prone to supervene owing to the interruption of the reflex arc and elimination of the blinking reflex. It was usual to wash out the eye with antiseptic lotion and stitch the lids together to lessen the risk.

I am, Sir, yours faithfully,

Manchester, March 14th, 1925.

S. R. WILSON.

POST-PARTUM AVULSION OF THE UTERUS.

To the Editor of THE LANCET.

SIR,—My friend, Dr. Miles Phillips, has done well in calling attention to Mr. Hopkins Walters's case of avulsion of the uterus, and I have done ill in overlooking it in my article on *Rupture and Avulsion of the Uterus at the Time of Labour: Cases which Recovered without Operation*. In the general index of the *Obstetrical Transactions* it is indexed under "avulsion" and "uterus," but not under "rupture." I ought, therefore, to have found it, and I regret very much that I did not refer to Mr. Walters's very valuable paper.

I am, Sir, yours faithfully,

March 14th, 1925.

HERBERT R. SPENCER.

THE ACIDIC VALUE OF THE URINE IN SKIN AND OTHER MANIFESTATIONS.

To the Editor of THE LANCET.

SIR,—Owing to absence abroad I was unable previously to reply to Dr. Whitfield's letter in your issue of Feb. 28th. From it I conclude either that he did not read my views set forth in your previous issue, or that he has failed entirely to grasp the essential points in my argument. His opening remarks: "If . . . the urine is sometimes hypoacid, and there is no evidence of acidosis in the blood, I do not see why one should be tempted to try alkalies" shows this clearly. For the essence of my view concerning the ætiology of the seborrhœic state is that in it there is an accumulation of acids (*not* uric acid), which, owing to an insufficient supply of alkaline bases, are with difficulty, or only partially got rid of by the kidneys, but are vicariously excreted via the skin and mucous membranes. The urine, as a matter of fact, is usually hyperacid to litmus in seborrhœic persons, but it may occasionally be hypoacid; when, however, in the latter case alkalies are administered it becomes for a while progressively more acid, presumably owing to the fact that, with the increased quantity of alkaline bases available, the retained acids are at once turned out by the kidney. Dr. Doble and I are not alone in our observations on this point; it is an established fact, and I cannot suggest any other explanation than the one I have offered. Dr. Whitfield then says: "It would be interesting to know what controls he has carried out on apparently normal people." I definitely stated in my previous letter that I have used myself and others, with no trace of seborrhœa, as controls.

With regard to his remark on acne, I have always insisted that the primary seborrhœic state, and the secondary infections to which it predisposes, must be differentiated, and in my letter I said: "When once an infection with micro-organisms has become established, the factors of sensitisation and specific lowered resistance to definite strains of bacteria come into play, and the administration of alkalies alone is not sufficient to cure." (This sentence was unfortunately included in the paragraph on cheilopompholyx, to which it did not belong.) In chronic acne, seborrhœic

dermatitis and sycosis, for example, it is necessary not only to treat the underlying seborrhœic state, but also to employ measures—local and otherwise—to overcome secondary microbial infection.

But the whole object of my investigations has been to define and seek the explanation of the primary seborrhœic state, on which these secondary manifestations depend, and so to prevent relapse when the latter are cured. Dr. Whitfield concludes his letter by asking, "Are we then to accept a theory based on results which we cannot corroborate, and to continue a form of treatment which in our hands and the hands of others has proved futile?" The matter cannot be dismissed in this supercilious fashion. There is but little theory in my views, and there will be still less when my chemical co-workers have determined the actual nature of the acids concerned; this should not be very difficult now that the acidity of the saliva has been demonstrated. Dr. Whitfield must remember that the observations of Dr. Doble and myself are based on the examination of a very large number of patients and urines, that we have both used numerous controls, and that our statements are clinical and biochemical facts.

Dr. Doble's observation on the recrudescence of the skin condition, when too much alkali is given, I believe, only refers to cases of true seborrhœic eczema—i.e., where the inflammatory lesions are not due primarily to microbic infection. In these cases I can understand that both an excess of alkali or of acid would aggravate the eczema, but I have never observed a similar phenomenon in the commoner seborrhœic manifestations, although one should always bear in mind the possible dangers of inducing alkalosis by excessive dosage.

With regard to Dr. Agnes Savill's letter, she, like Dr. Whitfield, exaggerates the mere administration of alkali at the expense of my real conception of the seborrhœic state. If she will read again my remarks on the *ætiology* of the seborrhœic state, she will understand why the case she quotes recovered, for she ordered precisely the diet I recommend (with which I have cured many mild seborrhœics, without giving alkali or other treatment), and corrected the constipation that is so important a factor. I am doubtful whether the parathyroid and the acne vaccine played any part in the happy result obtained. One does not desire to condemn one's patients to an unnatural intake of alkali, which is purely a temporary measure, but to check their seborrhœic tendency by teaching them those rules of dietary and personal hygiene, the neglect of which has produced their disorders. Her question as to the acidity of saliva I cannot answer, but she must remember that slight degrees of the seborrhœic state are so common in the unnatural conditions under which we live, that the absolutely normal adult is relatively a *rara avis*. I do not know whether the saliva is acid in true gout, which has nothing to do with the seborrhœic state, although the two may be associated.

In conclusion, may I briefly refer to three recent cases:—

(1) A medical man, with acne and intense seborrhœa, was given a powder composed of 18 parts basic phosphates and 82 parts of bicarbonates. He reported that his early morning urine was "like hydrochloric acid" and that it required ten teaspoonfuls of the above powder per diem to make the morning urine alkaline.

(2) A lady consulted me for seborrhœa of the scalp and face, and acne of the back. She complained that the sweat of her axillæ (which was sharply acid to litmus), and "the acid skin" of her back rotted her clothing. The saliva was strongly acid. She was unwilling to employ any local treatment during her stay in London, and was merely given alkali, a laxative, and a diet sheet. She returned in three weeks delighted, because, after taking the alkali for one week, her underclothing was no longer spoilt. The saliva was much less acid. What other possible explanation can there be in this case except an abnormal acid excretion via the sweat glands and skin?

(3) Dr. Ryle has kindly supplied me with notes on the following case. Miss R., aged 33. For years troubled with "seborrhœic eczema." Since October has had a dry mouth and throat, small ulcers on the tongue, a metallic taste in her

mouth, and has noted that the gold arch of her denture has changed in colour, becoming redder than before. Poor complexion, rough, greasy skin, intense seborrhœa capitis, patches of seborrhœic dermatitis on trunk and limbs. Saliva definitely acid to litmus. Urine very acid, equals 44 per cent. decinormal NaOH (phenolphthalein).

I am, Sir, yours faithfully,

H. W. BARBER.

Devonshire-place, W., March 9th, 1925.

THE PHYSIOLOGICAL ACTION OF MYDRIATIC ALKALOIDS.

To the Editor of THE LANCET.

SIR,—Years ago an article appeared in an English or American journal dealing with the chemical constitution and the physiological action of mydriatic alkaloids with, I think, special reference to atropine and the pharmacology of different samples. Being much interested at present in the last-named subject I am anxious to trace this article. You, Sir, have been kind enough to search your indices, but without success. I shall be very much obliged if any of your readers can help me to find it.

I am, Sir, yours faithfully,

ERNEST THOMSON, M.D.

33, Snowdon-place, Stirling, March 9th, 1925.

TWINS IN HEALTH AND DISEASE.

To the Editor of THE LANCET.

SIR,—Many readers of Prof. G. R. Murray's fascinating address upon this subject in THE LANCET of March 14th will doubtless recall examples from their experience to illustrate features of similarity often displayed by uniovular twins from the physical and the mental side. It is not particularly easy to advance examples of athletic equality—Prof. Murray gives as a solitary instance the Allen brothers in lawn tennis—for which reason I may be permitted to draw attention to the case of the twin brothers N. G. and C. M. Chavasse. Their athletic equality was really remarkable. They were sprinters of outstanding ability, and in 1907 they both represented Oxford against Cambridge in the hundred yards and quarter-mile races. I was assured by one of the brothers that they were quite undecided, in that season at any rate, that any difference existed between them and they had resolved to fight it out at Queen's Club. N. G. was successful in the shorter race, and by a happy chance victory went to C. M. in the quarter-mile. He won from his brother by a small margin, and I shall never forget the pretty spectacle of the twins racing each other round the last bend far ahead of their Light Blue rivals.

One recalls with reverence that N. G., who subsequently became a member of our profession, gave his life for his country in circumstances of such heroism that he was posthumously awarded a bar to the Victoria Cross which, together with the Military Cross, he had already gained and also the special Gold Medal of the British Medical Association. The military achievements of C. M., as a Chaplain to the Forces, supplied further evidence of similarity in another respect.—I am, Sir, yours faithfully,

Brook-street, W., March 14th. ADOLPHE ABRAHAMS.

HEXYL RESORCINOL.

To the Editor of THE LANCET.

SIR,—In view of the recent publicity given to the new synthetic compound hexyl resorcinol, we think it advisable to point out that this preparation is the subject of British patent applications by a foreign firm, and for this reason we have not manufactured it to meet the demands for supplies we have received from members of the medical profession.

We are, Sir, yours faithfully,

BURROUGHS WELLCOME & Co.

Snow Hill Buildings, London, E.C.,
March 13th, 1925.

Obituary.

JOHN CLELAND, M.D. EDIN., D.Sc. Q.U.I.,
LL.D. ST. AND., GLASG., AND EDIN., F.R.S.,

EMERITUS PROFESSOR OF ANATOMY, UNIVERSITY OF GLASGOW.

By the death of Prof. John Cleland, which took place at Chatham, where he was living in retirement, there has been removed from our midst a most prominent figure, a great teacher and worker in the field of science, and a philosopher. He will be deeply mourned by many generations of students, for few could resist the charm of his outstanding personality

JOHN CLELAND, M.D. EDIN.

and his great earnestness. Cleland was born in Perth in June, 1835; his life has therefore extended for practically 90 years, a long period when his great mental activity is taken into account. He was educated in the High School of Edinburgh and passed through his medical course in Edinburgh University, thereafter he studied for a year in Paris, returning to Edinburgh to graduate. His name was placed on the Medical Register in 1858. In Edinburgh he joined the staff of the University in the department of anatomy under the late Prof. Goodsir, whose original work greatly inspired the young demonstrator and whose memory he cherished throughout his life. A few years later he migrated to Glasgow, where he became senior demonstrator under the late Dr. Allen Thomson, at that time professor of anatomy in the University. In 1863 Cleland was transferred to the Chair of Anatomy in the then Queen's College, Galway, where he laboured incessantly for 14 years. His work must have been tremendous, for it embraced both anatomy and physiology and the surgical care of a large hospital. In addition he undertook the work, or a large part of it, of editing the seventh edition of "Quain's Anatomy," being one of three conjoined in the task, the others being William Sharpey and Allen Thomson. He also wrote a textbook of physiology, long a supreme favourite with

students all over the country, and he carried out a large number of researches, the results of which are published in numerous papers.

Cleland returned to Glasgow in 1877 as successor to Allen Thomson in the Regius Chair of Anatomy, in which he continued his active labours until his resignation in 1909, a period of 32 years. Of his life in Glasgow it is first to be said that he was loved and admired by his students. Physically he was a commanding personality, standing over 6 feet high and broad in proportion, and with a head so large and balanced with the rest as to give to the whole figure a striking appearance of nobility. He was intensely quick and sensitive, but so gentle and sweet in his demeanour that oftentimes a chastisement, called for and begun, ended in pardon and perhaps a blessing. He was a great and clear-thinking teacher. But perhaps the greatest service which he rendered to his students was the example of courage which he constantly set them in maintaining and defending his opinions on matters falling within his own sphere of work, against opposition, however fashionable its origin might be. His devotion and sacrifice to his mother, who for many years and until an extreme old age remained as head of his house, a great dame in Glasgow society, and for whose sake he postponed marriage until 1888, two or three years after her death, were the subject of admiration by all.

In the fields of biological science Cleland was a great worker and thinker. He was an ardent evolutionist, greatly admiring the work of Darwin but perhaps with a leaning to the theories of Lamarck. He has put forward his views in a series of papers entitled "Evolution, Expression, and Sensation," published together in one volume in 1881, and in 1887 in a volume of poetry entitled "Scala Naturæ and Other Poems" dealt with the same or similar topics. The philosophy of Darwin, eagerly assimilated by most of the scientific world, led many of Darwin's supporters into militant courses and not infrequently into materialistic conceptions, the latter more particularly in Germany. Cleland maintained a spiritual conception of life and nature, and for long was almost the only voice raised in this country against the irreligious tendencies of the age. But in the many controversies which ensued he fearlessly and brilliantly held his own. The whirligig of the times is bringing with it the justification of the courage of the great Glasgow philosopher and the proofs of the wisdom of his views. When Cleland passed into retirement his health was broken by many years of strenuous labour, and for 16 years he occupied practically a bed of sickness.

He is survived by a son, who during these final years, long drawn out, was his constant companion.

THE LATE DR. C. B. KER.

Dr. Alexander Joe writes as follows: "My colleagues and I at Colinton have read with great pleasure the obituary notice in THE LANCET with the appreciation by Dr. Andrew Balfour, who has told what manner of man our chief was when he knew him first 25 years ago. I think that, knowing Claude B. Ker after that lapse of time, there's not a man amongst us who would have expressed himself differently if he had been the possessor of Dr. Balfour's able pen. It is hard for us to realise that we shall see our beloved chief no more. His spirit so permeates the hospital that it seems as if he were away simply on one of his infrequent absences, and any minute we might expect to hear his well-known footfall along the covered corridors. Everyone has felt his loss as of a dear relative, for it is no exaggeration to say that he was loved and looked up to by everyone in the hospital. To those who have lived with him and worked with him the blow is a bitter one, and it is only now that we are beginning to realise how much of our work was of the nature of a personal service to our chief. He gave us a brilliant lead in both the amount and quality of our work, dealt with

us gently in the rough places, and was full of consideration for others, even in the most harassing circumstances. Old residents will remember him particularly at supper-time, when he would come in at the end of the day and talk about anything under the sun, take us into his confidence about men, matters, and books, and all the time reveal the sunny places in his extraordinarily well-stored mind. It is on occasions like these that we miss him most, and realise that his loss as a friend and as a guide to the manly exercise of our talents has made a gap that will never rightly be filled."

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—

At an ordinary meeting of the Council of the College on March 12th Sir John Bland-Sutton, President, in the chair, Mr. Arthur Percy Dodds-Parker, surgeon to Radcliffe Infirmary, Oxford, was admitted a member of the Court of Examiners.—The honorary gold medal of the College was presented to Mr. Richard Higgins Burne, together with a document declaratory of its award to him for his valuable services to the College as curator of the physiological department of the museum and his important contributions to biological science.—The John Hunter medal in bronze, together with the triennial prize for 1922-24, was presented to Mr. Wilfrid Edward Le Gros Clark for his researches in anatomy.—Mr. James Sherren was re-elected a representative of the College on the Senate of the University of London, and Dr. W. S. A. Griffith was re-elected a representative of the College on the Central Midwives Board.—The thanks of the Council were given to Mr. G. Buckston Browne, M.R.C.S., for presenting to the College an oil painting described as a portrait of John Hunter by Gainsborough, and to the Wellcome Historical Medical Museum for the presentation of some photographic reproductions of illustrations from the Life of John Hunter by Jesse Foote, surgeon, London, 1794.—A vote of condolence on the death of Dr. J. A. Ormerod was unanimously passed.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—

The annual meeting of the President and Council was held on March 17th, the Prince of Wales presiding. The accounts and report for the year 1924 were received and the annual report adopted.

NAVAL MEDICAL COMPASSIONATE FUND.—

A meeting of the subscribers of this fund will be held at 11.30 A.M. on April 17th at the Medical Department of the Navy, 68, Victoria-street, S.W. 1, to elect six directors of the fund.

ROYAL UNITED SERVICE INSTITUTION.—

A lecture entitled a New Principle in Health and Education will be delivered by Mr. Arthur Lovell on March 26th at 5.30 P.M., when Dr. Jane Hawthorne will also read a paper on the Results of Experiments with the New Principle at an Infant Welfare Centre in London. Lieut.-General Sir Aylmer Haldane will preside.

BRITISH MEDICAL ASSOCIATION: Scholarships and Grants in Aid of Scientific Research.—The Council of the British Medical Association is prepared to receive applications for research scholarships as follows: An Ernest Hart Memorial Scholarship, of the value of £200 per annum, for the study of some subject in the department of State medicine. Three Research Scholarships, each of the value of £150 per annum, for research into some subject relating to the causation, prevention, or treatment of disease. Each scholarship is tenable for one year, commencing on Oct. 1st, 1925. A scholar may be reappointed for not more than two additional terms. A scholar may hold a junior appointment at a university, medical school, or hospital provided the duties of such appointment do not interfere with his work as a scholar.

The Council is also prepared to receive applications for grants for the assistance of research into the causation, treatment, or prevention of disease. Preference will be given, other things being equal, to members of the medical profession and to applicants who propose as subjects of investigation problems directly related to practical medicine.

The conditions of the award of scholarships and grants are stated in the regulations, a copy of which, with the prescribed form, will be supplied on application to the Medical Secretary of the Association, 429, Strand, London, W.C. 2. Applications for the year 1925-26 must be made not later than Saturday, June 6th, 1925. Applicants for research grants must furnish the names of three referees who are competent to speak as to their capacity.

THE North-Western Tuberculosis Society will hold a meeting at the Skin Hospital, Quay-street, Manchester, on Thursday, March 26th, at 3.30 P.M., when a demonstration, arranged by Dr. G. H. Lancashire, of tuberculous skin cases and methods of treatment, including light treatment, will be given.

HUNTERIAN SOCIETY.—The third dinner meeting of the Hunterian Society will be held at Simpson's Restaurant, 2 and 3, Bird-in-Hand Court, 77, Poultry, Cheapside, on Monday, March 30th, at 7.30 P.M. Price of dinner, 3s. 6d. (excluding wines). Intention to be present, with or without guests, should be signified to Mr. A. E. Mortimer Woolf or Mr. A. Westerman. After dinner there will be a discussion on the Use and Abuse of Drugs, opened by Prof. W. E. Dixon and Dr. H. H. Dale.

ROYAL MICROSCOPICAL SOCIETY.—A meeting of the section of this society which has been formed to deal with the industrial applications of the microscope will be held at 20, Hanover-square, London, W., on March 25th at 7.30 P.M. Sir David Prain, F.R.S., will preside. Dr. James A. Murray, F.R.S., will give the second of a series of three lecture demonstrations on the Making of Microscopical Preparations. Prof. Percy Groom, F.R.S., will read a communication on the Microscopical Investigation of Fungal Attacks on Wood, and Mr. A. P. H. Trevelli and Mr. R. P. Loveland will speak on the Application of Microscopy to the Photographic Industry.

MAUDSLEY HOSPITAL.—The second part of the eighth course of lectures and practical instruction, instituted by the London County Council for a diploma of Psychological Medicine, will begin on April 1st. The course consists of series of lectures and clinical demonstrations on various aspects of mental diseases, as follows: Eight lectures on the Psychoneuroses, by Dr. Bernard Hart; eight lectures on Morbid Psychology and six demonstrations in Clinical Psychiatry, by Dr. Edward Mapother; six lectures on the Pathology of Mental Diseases, including Brain Syphilis, its Symptomatology and Treatment, by Sir Frederick Mott; eight lectures on the Practical Aspect of Mental Deficiency, by Dr. F. C. Shrubbsall; 12 clinical demonstrations in Neurology, by Sir Frederick Mott and Dr. F. L. Golla; six lectures on Crime and Insanity, by Dr. W. C. Sullivan; and lectures on the Legal Relationships of Insanity and Treatment, by Dr. C. Hubert Bond. The fees for the whole course are ten guineas, and for one single series of lectures two guineas. Further particulars as to the lectures may be obtained from the Director of the Pathological Laboratory, Maudsley Hospital, Denmark Hill, London, S.E. 5. In addition to the special lectures and demonstrations of the above course, there is opportunity for clinical experience and instruction available at the hospital. In particular there are a limited number of appointments available as clinical assistants; service in this capacity (either whole time or part time) is recognised by the various examining bodies as constituting the clinical experience required by the regulations for the diploma.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—A meeting was held at the Elizabeth Garrett Anderson Hospital on March 10th, Miss M. Chadburn in the chair, when Dr. Dorothy Hare read a paper on the Value of the Electrocardiograph to the Physician and Surgeon. She said that she proposed to discuss the general principles of the subject and not to describe the technical details of the apparatus. The one she worked at the Royal Free Hospital was similar to the original Waller instrument, invented in 1887, with the exception that the capillary electrometer was now replaced by the Einthoven string galvanometer. While no mechanical means of investigation should ever replace careful clinical examination, there did undoubtedly exist cases with few physical signs, in which the additional information supplied by the electrocardiograph was a weighty factor in the diagnosis. She spoke of the case of obtaining a reading without discomfort to the patient, the equipment at the hospital making it possible to carry out the whole process with the patient in bed if necessary. She then showed a series of interesting diagrams and records of clinical cases, selected in the main to bring out the special points which this method of investigation will elucidate. Dr. Hare pointed out that the normal tracing was by no means simple, and that the limits of variability of the normal had not yet been fully established. Secondly, cases illustrative of the value of the tracing in the determination of the condition of the myocardium were described. It was here that the electrocardiologist could be of help to the surgeon and obstetrician, as a definite opinion as to the patient's fitness for operation could be given from a study of the muscle element in the curve. Thirdly, a series of cases showing lesions of the conducting mechanism were then described. A short discussion followed, in which Dr. Dalby, Dr. Dobbie, Miss Alice Bloomfield, Dr. Lepper, Mrs. Flemming, and Miss Chadburn took part.

UNIVERSITY OF LIVERPOOL.—The University Council have invited Dr. J. E. W. MacFall, lecturer in toxicology, to accept the Chair of Forensic Medicine and Toxicology.

ROYAL INSTITUTION.—On Tuesday next, March 24th, at 5.15 P.M., Prof. A. S. Eddington will begin a course of two lectures at the Royal Institution on the Internal Constitution of the Stars; on Thursday, March 26th, at the same hour, Mr. T. Thorne Baker will deliver the first of two lectures on the Chemical and Physical Effects of Light, (1) Reproduction of Light Images by Photography, (2) Transmission of Light Images by Electricity; and on Saturday, March 28th, at 3 P.M., Prof. J. H. Ashworth will commence a course of two lectures on the Nervous System and Some Reactions. The Friday evening discourse on March 27th will be delivered by Sir Ernest Rutherford on Studies of Atomic Nuclei, and on April 3rd by Sir Daniel Hall on the Productivity of English Land.

SOCIETY OF SUPERINTENDENTS OF TUBERCULOSIS INSTITUTIONS.—The next ordinary meeting of this Society will be held at 122, Harley-street, at 3 P.M., on Monday, March 23rd, when a paper will be given by Dr. R. E. Wodehouse, secretary of the National Tuberculosis Association of Canada, on tuberculosis work in Canada, and another by Dr. Noel D. Bardswell on the results of an experiment on settling tuberculous men on the land. A discussion will also take place, initiated by Dr. Andrew J. Shinnie (Westminster) and Dr. Esther Carling (Peppard), on the weak points in the present scheme of treating tuberculosis at the public expense. It is hoped that a general practitioner will express the point of view of those in general practice.

THE MEDICAL OFFICER TO THE NUNEATON RURAL DISTRICT.—At a meeting of Nuneaton Rural District Council on March 11th a communication was read from the Ministry of Health pointing out that the local practitioner, whom the District Council wished to appoint as medical officer, did not hold either of the qualifications prescribed by Article 5 of the Sanitary Officers Order, 1922, whereas two of the candidates were specially qualified according to that Order. In the Minister's opinion any disadvantage which might result from residence outside the council's district would be outweighed by the advantage of obtaining the services of an officer with special experience and qualification in public health. On the information at present before him the Minister had decided that he would not be justified in exercising the power of dispensation reserved to him by Article 21 of the Order in respect of the appointment.

ROYAL MEDICAL BENEVOLENT FUND.—The annual meeting of this Fund was held at the Rooms of the Medical Society of London on March 17th, under the chairmanship of the President, Sir Thomas Barlow, when the report and financial statement for the year 1924 were submitted and approved. The report recorded an increase of £1000 in new subscriptions, which was balanced, however, by a similar sum lost, principally through the death of subscribers. The grant income showed an increase of £30 only, and the total income an increase of £130. The Committee of Management point out that the applications for help became more numerous each year, while the increase in the cost of living makes it necessary to give larger grants than formerly, and add: "The amount of distress and starvation of which many of the older applicants complain is so distressing that if it could only be better known to the profession there would at once be a large wave of benevolence which would pour money into the funds of the society for relief." During the year 343 persons have been relieved by grants and 147 by annuities, while the demands on the Fund steadily increase year by year quite out of proportion to the income. The income derived from subscriptions and donations amounted to £4846, and from invested property to £4343. The total income available for distribution was £9573, a decrease of £354 on the preceding year. The amount expended in grants was £5001, and in annuities £3476, making a total distribution of £8468, or an increase of £780. It was announced that the War Emergency Fund, part of which has been used to educate the children of medical men who had suffered in their incomes owing to the war, would come to an end next year. A special tribute was paid to the Ladies' Guild for its invaluable help, and it was mentioned that the British Medical Association had collected subscriptions of over £1100, while the medical and lay press had helped the Fund considerably. The deaths of Sir Clifford Allbutt, Sir Anderson Critchett, Sir Frederick Needham, Dr. G. E. Haslip, and Mr. J. H. Morgan meant the loss of valuable supporters of the Fund, the two last named being members of the Committee of Management. Sir Thomas Barlow was re-elected as President, Sir Charters J. Symonds as hon. treasurer, and Dr. G. Newton Pitt as hon. secretary.

RACIAL RESEARCH IN SWEDEN.—A lecture with illustrations will be given, entitled "Races and Racial Research in Sweden," on Monday next, March 23rd, at 8.30 P.M., by Dr. W. Krauss, in the rooms of the Royal Anthropological Institute, 52, Upper Bedford-place, London, W.C. The chair will be taken by Dr. F. C. Shrubbsall, and the lecture will be accompanied with numerous illustrations. Dr. Krauss is attached to the Swedish State Institute for Race Biology.

NEW SUSSEX HOSPITAL FOR WOMEN AND CHILDREN. On the occasion of the annual meeting of the governors of this institution at Brighton, a hospital entirely officered by women doctors, Dr. Mary Scharlieb, C.B.E., opened the new X ray department, which had been installed thanks to the generosity of Mr. C. H. Corbett and Mr. Herbert E. Corbett. The present premises in Windlesham-road were only opened in August, 1921, but already there is need for extension from 30 beds to 50, and a preliminary appeal is being issued for £20,000 to enable another wing to be built. The year's work at the institution marked a great increase in patients, particularly those in the out-patient department. The balance-sheet was in a satisfactory position.

PEOPLE'S LEAGUE OF HEALTH.—The last of a series of nine lectures on What We Should Eat and Why, which are being given under the auspices of the League, will be delivered by Prof. W. E. Dixon on Wednesday, March 25th, at 6 P.M., at 11, Chandos-street, Cavendish-square, London, W.1. The subject of Prof. Dixon's lecture is Food Preservation and Adulteration.—The ninth lecture of the Sims Woodhead series of constructive educational health lectures will be delivered by Sir Frederick Mott on Brain and Nervous System, at 6 P.M., on Monday, March 23rd, at the headquarters of the National Union of Teachers, Hamilton House, Mabledon-place, W.C.1. The tenth, and final, lecture will be given by Dr. Tredgold on Development and Function of Mind, on Monday, March 30th, at the same hour and place.

MEDICAL SOCIETY OF LONDON: ANNIVERSARY DINNER.—The 152nd anniversary dinner of this Society was held in the Grand Hotel on March 11th, the President, Dr. Eustace M. Callender, in the chair. The toast of "The Medical Society of London" was given by Sir StClair Thomson in a happy speech illuminated with many quotations from Shakespeare and from the writings of the founder of the Society—Lettsom. Referring to the President, he said that Dr. Callender was the first general practitioner to hold that office since Lettsom himself occupied the chair. Dr. Callender, in reply, referred to Lettsom's opinion that "nothing had contributed more to the advancement of science than 'literary' societies." He spoke of the danger of specialists interpreting signs and symptoms in terms of their own specialty, and, in illustration, related a joke which appeared in the French comic press about 1880, when under the influence of Koch attention was being directed less to the patient than to his disease, where two "specialists" were depicted assuring a widow that her husband had died cured. The toast of "The Forces" was given by Sir Humphry Rolleston, and was responded to by Surgeon Vice-Admiral Joseph Chambers, Director-General of the Navy. "The Visitors," coupled with the names of Lord Riddell and Mr. Basil Hall, were proposed in amusing vein by Dr. Herbert Spencer. Sir Charters Symonds gave "The President," and Dr. Callender, in the course of his reply, paid a tribute to the work of the two secretaries of the Society, Prof. F. Langmead and Dr. J. E. H. Roberts.

TUBERCULOSIS SOCIETY.—An ordinary meeting of this society will be held at 1, Upper Montague-street, Russell-square, to-day (Friday) at 8 P.M. Dr. W. H. Dickinson, tuberculosis officer, Newcastle-on-Tyne, will give a paper, illustrated by lantern slides, on the League of Nations Post-graduate Course for Tuberculosis Workers.—The provincial meeting of the society will be held in Cambridge on April 2nd, 3rd, and 4th, in the pathological lecture theatre of the University. The following papers will be read:—April 2nd: Prof. W. E. Dixon, Treatment of Disease with Heavy Metals and Bactericidal Agents; and Dr. J. E. A. Lynham, X Rays in the Diagnosis of Pulmonary Tuberculosis. April 3rd: Dr. R. C. Matson, National Tuberculosis Association (America), (1) End-results and Limitations of Artificial Pneumothorax, (2) the Role of Thoracoscopy, Thoracoplasty, and other Surgical Procedures; Mr. Henry Platt (Manchester), Forms of Arthritis simulating Tuberculosis; Sir Henry Gauvain, the Present Position of Light Treatment in Surgical Tuberculosis; Dr. Louis Cobbett, Racial Susceptibility and Resistance to Tuberculosis. On April 4th Dr. Cobbett and Dr. Stanley Griffith will give a demonstration of pathological specimens, and, by the invitation of Dr. Jane Walker, a visit to East Anglian sanatoria will be made. Information as to lodging accommodation and cheap railway fares may be obtained from F. J. C. Blackmore, hon. secretary, at 138, Herbert-road, Plumstead, London, S.E. 18.

Parliamentary Intelligence.

HOUSE OF COMMONS.

TUESDAY, MARCH 10TH.

Mental Hospitals.

Mr. TAYLOR moved "that in the opinion of this House a reform of the conditions existing in mental hospitals is of urgent importance." He said that there was no need to wait for the report of the Royal Commission before giving effect to the recommendations of the Departmental Committee which reported last July. When they considered the physical and mental strain under which the magnificent body of men and women who formed the staffs of mental hospitals did the dirty work of society, a work which would be repulsive were it not for their gift of human charity, kindness, and love, when they considered that these people might be subjected to physical violence and the indescribable filth among which they had to pass their daily lives, he thought they were entitled to expect from the rest of society better treatment than they were getting to-day. The average wage of a fully qualified and trained male nurse in charge of a ward was less than the minimum wage of a police probationer. He thought that a 48-hour week was the right thing for mental hospital staffs, but the Committee which examined this specific problem 12 months ago reported in favour of 56 hours, giving a day and a half compulsory holiday, and he suggested to the Government that the Board of Control could by judicious pressure bring up the worst asylums to the level at any rate of the recommendations of that Committee. A fortnight ago, he said, he went through an asylum and discovered about 30 boys and girls who ought not to have been there at all. According to the medical superintendent of that institution, they were capable of being trained and educated in some degree, and they ought to have had an entirely different environment. As a matter of fact these children were in the wards with adult patients, with idiots, and with lunatics of every degree of suffering. The medical superintendent was a most humane and efficient administrator, but the difficulty was that there was no alternative accommodation. He had made representations to the local authorities, but they were up against the necessity for embarking on large capital expenditure. He hoped the Government would see their way to assist local authorities in this matter, because even the 60 per cent. grant which under the Mental Deficiency Act they could make towards capital expenditure of this kind was not sufficient in view of the financial position of many of the local authorities.

Mr. R. RICHARDSON, in seconding the motion, advocated placing mental cases under the charge of the health committees of the local authorities. He also wished to call attention to the insufficiency of the medical staff. In one hospital he knew very well there were only four doctors to attend to 400 patients. If there was a larger medical staff he believed that instead of 19 or 20 per cent. of recoveries that could be easily increased to 40 or 50 per cent. in the near future. As regarded nurses nearly every hospital with which he was acquainted was under staffed.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) said the Royal Commission, which was now sitting, was empowered to examine many of the points raised by Mr. Richardson. He hoped, therefore, that the hon. Member would not think that he was wanting in sympathy when he said that it would be better to await the judgment of that Commission before indicating any views which he held on the matter. He anticipated that the report of the Commission would be forthcoming next year. As soon as it was received it would obtain the immediate attention of the Ministry of Health. With regard to the question of the conditions of mental hospital staffs, he agreed that the work of mental nurses did not receive the public commendation that it deserved. These people ought to command every sympathy from the House and from the local authorities. So far as the Ministry of Health was concerned, they desired in every possible way to see that they received every sympathy and carried out their duties under the most favourable conditions. The Board of Control was most anxious that, at any rate, many of the recommendations of the Committee which had been referred to should be adopted by the local authorities. The Board had done and would do all in their power to improve the conditions of people who had such difficult tasks to carry out in their everyday life. But the difficulty was that the Board had no powers to enforce on local authorities better terms and conditions with regard to mental nursing. They would, however, continue, so far as they could, to bring the Committee's recommendations to the notice of local authorities.

Replying to a question by Mr. TAYLOR, Sir KINGSLEY WOOD said he would consider whether he could confer with

the local authorities in the worst areas with a view to finding some method of meeting the most pressing needs. The motion was by leave withdrawn.

WEDNESDAY, MARCH 11TH.

Blind Persons in England and Wales.

Mr. GROVES asked the Minister of Health the number of persons affected by the application of the Blind Persons Act, 1920; the number at present employed in the various workshops; the average wages paid; and the number of blind persons in receipt of the old age pension.—Mr. NEVILLE CHAMBERLAIN replied: The total number of known blind persons in England and Wales on June 30th, 1923, was 36,518. The number employed specifically in workshops is approximately 2090. The average wage—that is, the wage earned at the trade-union or other standard piece-work rates, is approximately 20s. a week, but, in addition to the wage actually so earned, augmentation is in all cases paid to blind workers. The number of blind persons between 50 and 70 years of age who were in receipt of pensions under Section 1 of the Blind Persons Act, 1920, was 11,525 on Dec. 31st last.

Foot-and-Mouth Disease Research.

Mr. STEPHEN MITCHELL asked the Minister of Agriculture the expenditure in connexion with the Foot-and-Mouth Disease Scientific Committee since March of last year; and what the available funds for this purpose amounted to.—Mr. WOOD replied: A grant of £10,000 from the Development Fund was sanctioned by the Treasury for the work of the Foot-and-Mouth Disease Scientific Committee during the present financial year, and of this sum £5500 was expended up to Feb. 28th. A grant of £15,000 has been approved to meet the expenses of the Committee in the coming financial year; this is the sum estimated by the Committee to be required.

Danger of Patent Medicines.

Mr. GROVES asked the Minister of Health whether he had considered the conditions under which patent medicines were manufactured and sold in this country as compared with other countries; whether he was aware that ill-informed persons were attracted by advertisements and thereby avoided proper medical attention; and whether he would consider what steps he could take to ensure public health and safety in this respect.—Sir KINGSLEY WOOD replied: The question of some statutory regulation of the conditions in which patent medicines are advertised and sold is under consideration, but unless a substantial measure of agreement can be secured, my right hon. friend does not anticipate that it will be possible to introduce legislation during the present session.

Health of Unemployed Men.

Mr. GROVES asked the Minister of Health if he had any information in regard to the health of the unemployed men and women of the country who had been out of employment for two years and upwards; and whether, in view of the fact that such persons might be assumed to be quite outside the National Health Insurance benefits, he had considered the issue of instructions to the various boards of guardians to arrange special medical attention to persons so affected.—Sir KINGSLEY WOOD replied: I think the hon. Member has overlooked the effect of the Prolongation of Insurance Act, 1921, which is still in force. In view of this Act it has not been thought necessary to make any special inquiries as to the health of unemployed persons, and my right hon. friend is not aware that there is any need for the issue of such instructions as are suggested in the last part of the question.

Condemned Houses in Occupation.

Mr. HORE-BELISHA asked the Minister of Health whether, in view of the necessity of obtaining an accurate estimate of the number of houses required, he could see his way to obtain statistics of the number of condemned houses which were still inhabited and of the number of persons occupying these houses; including children, particularly, in view of the fact that without these statistics no accurate estimate of the housing shortage could be made.—Sir KINGSLEY WOOD replied: Information is already furnished to my right hon. friend in the annual reports of medical officers of health as to the number of houses found, after inspection, to be unfit for human habitation. According to the last reports the number of such houses reported during the year 1923 was 14,367. My right hon. friend does not consider that the value of the further information asked for in the hon. Member's question would be commensurate with the labour and cost involved in obtaining it.

Employment of Pensions Medical Officers.

Colonel Sir ARTHUR HOLBROOK asked the Minister of Pensions, with reference to his promise that medical officers discharged from the medical staff employed by the Ministry would be given sessional work on medical boards, whether

he would give definite instructions to heads of the various areas that this practice must be continued.—Viscount CURZON replied: My hon. and gallant friend's suggestion is in accordance with the existing practice of the Ministry and instructions are being issued accordingly.

THURSDAY, MARCH 12TH.

Closing of Convalescent Centres.

Colonel DAY asked the Minister of Pensions what convalescent treatment and training centres had been closed in the past 12 months and where situated; whether it was proposed to close the remaining treatment and training centres; and, if so, on what dates.—Viscount CURZON replied: The centres at Barry and Blackpool were closed during 1924. The centre at Epsom is being closed this month. The remaining centre at Birmingham is still required and no date can at present be assigned for its closing.

Neurasthenics at Saltash.

Colonel DAY asked the Minister of Pensions the total cost per head, including establishment, medical attendance, and food, of the patients in the institution for neurasthenics at Saltash, Cornwall; and whether, if the cost be higher than would be the case if the men were given 100 per cent. pensions, he would, seeing that most of the men had been under treatment and away from their homes the greater part of the time since their discharge, consider the desirability of awarding life pensions and permit the men to be restored to their families.—Viscount CURZON replied: The total cost of the treatment given in the institution referred to is 34s. a week per head, exclusive of the personal allowances payable to the men and their families. If such allowances are included in the cost, the amount would, on an average, be in excess, and necessarily so, of the average amount that would be drawn by a pensioner on a pension for total disablement. The patients in this institution are admitted for the purpose of undergoing a specific course of treatment, and it would, therefore, not be in the interests of many of the cases to adopt the course suggested by the hon. and gallant Member, even if it were otherwise practicable. It is not, however, the intention of the Ministry that cases should remain indefinitely or unnecessarily in this or any other institution, and where they can suitably be dealt with by discharge to their homes with an appropriate rate of pension, this course is adopted.

Bonus for Ex-Service Medical Officers.

Colonel Sir ARTHUR HOLBROOK asked the Minister of Pensions whether he would consider the grant of a bonus to ex-Service medical officers now in the employ of the Ministry and under notice of discharge in cases where these officers had five years' service or more under the Ministry, seeing that those fortunate enough to be retained were to receive a rise of pay of £50 per annum in lieu of a bonus based on the number of years served.—Viscount CURZON replied: It is not customary for temporary civil servants to be paid a bonus on discharge, and my right hon. friend would not feel justified in urging upon the Chancellor of the Exchequer that the temporary medical officers of the Ministry of Pensions should be specially privileged in this respect. The hon. and gallant Member is under a misapprehension in thinking that the increase referred to in the last part of his question is being granted in lieu of any such bonus. It has been decided upon as part of a general scheme for the future remuneration of the medical officers of the Ministry, which has been framed after consultation with their staff association.

Patients in Mental Hospitals.

Lieut.-Commander KENWORTHY asked the Minister of Health how many persons were at present confined in mental hospitals; and how many of these were maintained solely at the public expense.—Mr. NEVILLE CHAMBERLAIN replied: On Jan. 1st, 1925, there were 111,200 persons confined in institutions for the insane in England and Wales; 102,313 were maintained at the public expense, but in many of the rate-aided cases contributions are recovered from the relatives.

Hospital Contributions Held Up.

The Marquess of HARTINGTON asked the Home Secretary whether his attention had been called to the fact that the management of a company in the hands of the receiver was unable to hand over to a hospital money held by it as employees' contributions to a joint hospital fund, and that in some cases money deducted from wages for the purpose of payment to hospitals had been held up nearly two years; and whether, having regard to the fact that such money could not under any circumstances be regarded as part of the assets of a company, he could arrange for it to be paid over to hospitals without unnecessary delay.—Sir P. CUNLIFFE-LISTER (President of the Board of Trade) replied: If my noble friend will give me particulars of any specific case which he has in mind I will have it looked into.

Deaths from Influenza.

Sir ALFRED BUTT asked the Minister of Health the number of deaths caused by influenza or its complications in London during January and February, 1925; whether these deaths had any correlation with age, occupation, or locality; and whether, in view of a probable return of the epidemic and its crippling effect on industry, he would consider any amendment of the National Health Insurance Acts to encourage the withdrawal of early influenza cases from factories, workshops, and offices during the most infectious period.—Mr. NEVILLE CHAMBERLAIN replied: The total number of deaths in London during January and February, 1925, notified as due to influenza, was 480, which is equivalent to 649 per million of the population per annum. I am sending detailed figures to my hon. friend showing the number of deaths in each of the London and metropolitan boroughs, and also the number in age-groups. Information as to occupations could not be given without a re-examination of the entry relating to each individual death. As regards the last part of the question, I think that an amendment of the National Health Insurance Act on the lines suggested would not be practicable. The effect of the Act is already in the direction desired by the hon. Member, inasmuch as it encourages workers to seek prompt medical advice as soon as they begin to feel ill, and by providing cash payments during absence from work owing to illness it alleviates the financial loss through such absence.

Opium Exports from India.

Mr. SCURR asked the Under Secretary of State for India the amount and value of the opium exports of India for the last five years, and how these exports were distributed to various countries.—Earl WINTERTON replied: The following is a statement of the number of chests exported from India to various countries during the years 1919-23. Figures for 1924 are not at present available.

Destination.	1919.	1920.	1921.	1922.	1923.
Singapore ..	4155	3090	3010	1820	2100
Hong-Kong ..	1009	180	120	150	240
Colombo. . .	50	60	70	60	30
Batavia . . .	2000	2900	2300	1800	900
Sydney . . .	1	—	—	—	—
London . . .	1700	100	—	—	—
Kobe	1150	900	150	50	150
Bangkok . .	1700	1700	1700	1650	1600
Saigon	1920	950	1655	1700	2975
Mauritius . .	—	35	—	—	—
Macao	—	531	440	500	240
Yokohama . .	20	—	—	—	—
Sarawak . . .	—	—	—	55	125
British North					
Borneo . . .	226	176	240	60	84
Bushman . .	—	—	85	283	100
Total	13,931	10,622	9770	8128	8544

The total value of the opium exported from India during the above five years is as follows. Particulars of the value of the opium exported to each individual country are not available.

Year.	Total value (Rs.).	Year.	Total value (Rs.).
1919 ..	3,42,16,390	1922 ..	2,96,36,088
1920 ..	3,28,35,830	1923 ..	3,44,12,829
1921 ..	3,16,30,584		

Colonial Revenues from Opium.

Mr. CAMPBELL asked the Secretary of State for the Colonies what proportion in the total revenues, for the last year for which figures were available of the Straits Settlements, Federated Malay States, North Borneo, and Brunei respectively, was derived directly or indirectly from opium.—Mr. AMERY replied: For the year 1923, which is the latest year for which complete figures are available, the revenues derived from opium by the Governments of the Straits Settlements, the Federated Malay States, and Brunei formed 45.4 per cent., 16.9 per cent., and 18.24 per cent. respectively of the total revenues collected by these Governments; as regards North Borneo, the latest year for which I have information is 1921, when the proportion was 12.3 per cent.

Infantile Mortality at Market Drayton.

Sir CHARLES OMAN asked the Minister of Health whether he had received a report from the medical woman inspector as to the high rate of infantile mortality at Market Drayton; whether the report had been published; and what was the rate of infantile mortality in that union for 1924, as compared with that of the neighbouring unions of Wellington and Newport and with that of Shropshire as a whole.—Mr. NEVILLE CHAMBERLAIN replied: The answer to the first part of the question is in the affirmative, and to the second part in the negative. I have, however, communicated to the

county council certain suggestions arising out of the report and am now awaiting their reply. As regards the last part of the question, figures are not available for unions, but the following are the figures for 1924 for the urban districts mentioned in the question and the county as a whole:—

Urban district.	Births.	Deaths (under one year).	Infantile mortality (per 1000 births).
Market Drayton ..	77	7	91
Wellington . . .	135	4	30
Newport . . .	48	2	42
County of Salop ..	2119	127	60

Asylums under Local Authorities.

Major GLYN asked the Minister of Health how many asylums for lunatics were under the administration of local authorities now and for the years 1900 and 1914; what was the total number of inmates now and for the same years; and what was the present-day cost of maintaining these institutions.—Mr. NEVILLE CHAMBERLAIN replied: The figures are as follows:—

Year (1st Jan.).	Number of inmates.	Number of institutions.
1900	74,004	79
1914	105,504	97
1925	105,399	97*

* This figure does not include Ewell Epileptic Colony—loaned to Ministry of Pensions; and Maudsley Hospital, which provided accommodation on Jan 1st, 1925, for 146 uncertified patients.

The cost of maintenance (excluding loan charges) during the year ending March 31st, 1924, was £6,242,284.

FRIDAY, MARCH 13TH.

Summer-Time Bill.

Lieut.-Colonel A. L. WARD moved the second reading of the Summer-Time Bill, a measure providing for the permanent adoption of summer-time to begin on the Sunday following the first Saturday in April and end on the Sunday following the first Saturday in October.

Mr. A. RAWSON seconded.

Sir H. HOPE moved the following amendment: "That this House, while approving the introduction of summer-time, declines to give a second reading to a Bill which, unless it is limited to the months of May, June, July, and August, must inflict grave injury to the industry of agriculture."

Replying to Mr. B. PETO, the Speaker said that the effect of the amendment would undoubtedly be to kill the Bill, and he imagined it was so intended.

Dr. LITTLE said that it was at the request of the medical members of his constituency (London University), and as a medical man himself and a hospital physician in London for 25 years, that he supported the fullest application of this Bill. The opposition to the Bill came largely from agriculturists, who were in the fortunate position of spending all their lives in the fresh air, and who hardly realised how very selfish their action was in preventing some little opportunity of the same kind to the classes who were not in such a position. He urged from the medical point of view that they were on the eve of great extensions of knowledge of the properties of sunlight. His branch of medicine had led to a special study of its effects, and anyone who visited the light department of any of the great London hospitals would see the transformation of human wrecks into reasonably healthy persons as the result of sitting for a half an hour three times a week in front of a feeble imitation of sunlight coming from a carbon arc lamp. The importance of sunlight and the importance of fresh air could not be over-estimated, and both would be immeasurably increased for large numbers of people by this Bill. The study of the pathological effects of fresh air and sunlight showed that they had an enormous influence on nutrition generally. He would like to see people wear less clothes in the sunlight, but as they could not go the whole extent, he hoped they would clothe themselves in such a way as to get as much benefit as possible from the sunlight and fresh air.

Sir W. JOYNSON-HICKS (Home Secretary) said that the Government proposed to leave the second reading of the Bill to a free vote of the House. If the second reading was carried and the measure passed through Standing Committee—where he hoped there would be no organised opposition—the Government would take it up and give the necessary facilities for its further passage. But on the report stage he would arrange for a free vote to be taken in the House as to the dates of the beginning and ending of the summer-time period.

After further debate the amendment was rejected by 289 votes to 63—majority against 226. The Bill was then read a second time.

MONDAY, MARCH 16TH.

Medical Referees and Hospital Cases.

Mr. BENJAMIN SMITH asked the Home Secretary whether a medical referee under the Workmen's Compensation Acts who was also on the staff of a voluntary hospital was not permitted to give a report on a case under his care at that hospital; and, if so, whether, seeing that this might involve injustice to the patient examined, as no other doctor could know as much of the case, he would consider the advisability of withdrawing the instruction or regulation.—Mr. LOCKER-LAMPSON (Under Secretary to the Home Office) replied: There is no specific Home Office instruction or regulation which prevents the doctor in such a case giving the workman or the employer a report on the condition of the workman, but if a referee is employed in any case by or on behalf of either party, he is precluded by the Statute from acting subsequently as referee in that case. It is also generally undesirable that referees should act for either party in compensation cases, especially cases which are the subject of dispute. My right hon. friend will, however, consider the matter further in the light of the hon. Member's representation, and if he has any particular cases in mind, the Home Secretary would be glad to be furnished with the details.

Mentally Defective Children in Scotland.

Mr. STEPHEN MITCHELL asked the Secretary for Scotland what arrangements existed for the education of slightly mentally defective children in the towns and also in the rural districts of Scotland.—Sir J. GILMOUR replied: The provision of schools and classes for mentally defective children in the towns and rural districts of Scotland as at July 31st, 1923, is stated in Table 4 of the latest "Return showing Grant-earning Day Schools and Institutions." Since the date of that return the number of schools and classes has been increased, but the final figures are not yet available.

Milk and Dairies Act, 1915.

Mr. BARNES asked the Minister of Health whether, in view of his decision to allow the Milk and Dairies Act, 1915, to become operative from Sept. 1st next, those provisions of the Act which would be administered by order of the Minister would all be enforced from that date; and, if so, whether he would publish drafts of the Orders at an early date and arrange for consultation with the interests concerned before submitting the draft Orders to Parliament.—Sir KINGSLEY WOOD replied: My right hon. friend is unable at present to say on what date the Orders to be made in pursuance of the Milk and Dairies Act, 1915, will come into operation, but, as the hon. Member is no doubt aware, until the new Orders are made the existing Orders will continue in force. It is certainly the intention of my right hon. friend to consult the interests concerned before any new Orders are laid before Parliament.

Elimination of Bovine Tuberculosis.

Mr. HURD asked the Minister of Agriculture whether, following upon the visit of his scientific advisers to North America, he proposed to adopt in this country such administrative measures for the elimination of bovine tuberculosis as had proved successful in the United States and Canada.—Captain HACKING (Vice-Chamberlain of the Household) replied: My right hon. friend has at present under consideration means for the elimination of bovine tuberculosis, and he is proposing to introduce shortly a measure on the lines of the Tuberculosis Order of 1914, which is a necessary first step in any procedure of the kind.

Hospitals for British Troops in India.

Sir PHILIP RICHARDSON asked the Under Secretary of State for India whether any report had been received from India as to giving effect to the recommendations of the British Station Hospital Committee of 1918; and when he expected to take action to improve the standard of comfort and accommodation in hospitals for British troops in India.—Earl WINTERTON replied: I am sending the hon. Member a detailed statement supplied by the Government of India. Progress is being made as fast as financial conditions permit.

TUESDAY, MARCH 17TH.

Sanatoria Accommodation in Glasgow.

Mr. COUPER asked the Secretary for Scotland whether any complaints had been received in regard to the sanatoria accommodation in Glasgow; how many persons were waiting for admission to sanatoria in Glasgow on March 7th; and what was the longest period any of these applicants had been waiting for admission.—Sir J. GILMOUR replied: The reply to the first part of the question is in the negative. On March 7th the number of cases of pulmonary tuberculosis awaiting admission to institutions was 71, of which 23 were cases recommended for sanatorium treatment. Normally the period of waiting for pulmonary cases recom-

mended for institutional treatment does not exceed from 10 to 14 days. During winter pressure a case may wait for as long as two months, but regard is had in every case to the patient's condition and in the event of urgency admission would be arranged without delay.

Medical Women and the Post Office.

Miss WILKINSON asked the Postmaster-General whether he was aware that the Post Office was the only Government department which paid its women doctors less than its men doctors for similar work; and whether, in view of the fact that the Post Office advertisements for posts at present vacant were being refused by the medical journals in consequence, he would bring his department into line with other departments in this matter.—Sir W. MITCHELL-THOMSON replied: The conditions under which women medical officers are employed in the Post Office are not analogous with those of other departments. The question of equal pay for men and women is one which affects the whole of the Civil Service, and I am not in a position to recommend an exception in respect of this particular class of civil servant.

Mental Deficiency Bill.

Sir LESLIE SCOTT introduced the Mental Deficiency (Amendment) Bill, a measure to amend Section 7 of the Mental Deficiency Act, 1913, for the purpose of enabling a defective to be removed from an institution for the purpose of being placed under guardianship.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, March 23rd.

MEETING OF THE SOCIETY: at 5.30 P.M.

Special Discussion (continued from Feb. 16th) on

Non-specific Disturbances of Health Due to Vitamin Deficiency.

Speakers:

Dr. William Hunter, Dr. Robert Hutchison, and others.

ODONTOLOGY: at 8 P.M.

Casual Communication:

Mr. G. J. Harbrow: A Dental Cyst in Connexion with a Deciduous Tooth.

Paper:

Mr. A. Livingston: The Permeability of Enamel.

Tuesday, March 24th.

SURGERY
MEDICINE
PATHOLOGY

Special Discussion: at 8 P.M.
The Treatment of Septicæmia.

Openers:

Sir Thomas Horder (Medicine), Mr. R. P. Rowlands (Surgery), and Dr. L. Colebrook (Pathology).

Wednesday, March 25th.

COMPARATIVE MEDICINE: at 5 P.M.

Paper:

Sir Stewart Stockman: A Review of Some Problems of Foot-and-Mouth Disease (with lantern demonstration).

Thursday, March 26th.

EPIDEMIOLOGY AND STATE MEDICINE: at 5.30 P.M.

Paper:

Dr. W. L. Burgess (M.O.H. Dundee): An Outbreak of Food Poisoning.

UROLOGY: at 8.30 P.M.

Clinical and Pathological Evening.

Members wishing to exhibit specimens are requested to notify the Hon. Secretary (Mr. Sydney G. MacDonald, 51, Queen Anne-street, W.) as soon as possible.

Friday, March 27th.

STUDY OF DISEASE IN CHILDREN.

Clinical Meeting at 4.30 P.M. at the National Hospital for the Paralyzed and Epileptic, Queen-square, W.C.

Cases will be shown.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, March 23rd.—8.30 P.M., Discussion on Oxaluria, to be introduced by Mr. L. Bathe Rawling, followed by Sir William Wilcoxon and others.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.
WEDNESDAY, March 25th.—7.30 P.M., Dr. J. A. Murray: Imbedding and Section-Cutting.

HARVEIAN SOCIETY OF LONDON, Town Hall, Paddington Green, W.

THURSDAY, March 26th.—8.30 P.M., Discussion on Obstruction of the Colon. To be opened by Sir Crisp English, followed by Mr. T. P. Legg, Dr. Arthur Hurst, Mr. Lockhart-Mummery, Mr. Gordon-Taylor, Dr. Montague Smith, and others.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, Cavendish-square, W.

FRIDAY, March 27th.—8.30 P.M., Discussion on Gonococcal and Syphilitic Infections of the Eye. To be opened by Mr. Bishop Harman, followed by Mr. Cyril Hudson and Mr. T. H. Benians.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

MONDAY, March 23rd, to SATURDAY, March 28th.—WEST LECTURE HALL, Royal Society of Medicine. Monday, March 30th, at 5.30 P.M., Mr. Ernest Clarke: Myopia—its Diagnosis and Treatment. Wednesday, April 1st, at 5.30 P.M., Dr. Robert Knox: Demonstration on X Rays in the Diagnosis of Lesions on the Right Upper Quadrant of the Abdomen.—BROMPTON HOSPITAL FOR DISEASES OF THE CHEST. Second week as per syllabus.—CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd-street, W.C. Lecture-demonstrations in Diseases of the Eye. Daily from 1.30 P.M.—NORTH-EASTERN FEVER HOSPITAL, St. Ann's-road, Tottenham. Wednesday and Saturday, 11 A.M., Demonstrations and Treatment of the Acute Infectious Diseases, by Dr. Frederic Thomson.—ROYAL NORTHERN HOSPITAL, Holloway-road, N. Intensive Course (first week).—CHELSEA HOSPITAL FOR WOMEN. Special Course as per syllabus. Mostly afternoon work.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, March 23rd.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2 P.M., Mr. Addison: Surgical Wards.

TUESDAY.—11 A.M., Mr. Endean: Venereal Diseases. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.

WEDNESDAY.—11 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—11 A.M., Sir Henry Simson: Gynaecological Wards. 2 P.M., Mr. MacDonald: Genito-Urinary Dept. 2 P.M., Mr. Bishop Harman: Eye Dept.

FRIDAY.—11 A.M., Dr. McDougal: Electrical Dept. 10.30 A.M., Dr. Dowling: Skin Dept. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

SATURDAY.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturday, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

FRIDAY, March 27th.—4.30 P.M., Dr. W. Jenkins Oliver: Some Common Dermatoses of Children.

Daily, In-patient and Out-patient Cliniques, Operations, Cliniques in Special Departments, &c.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: FEB.—MARCH, 1925.

CLINICAL LECTURES AND DEMONSTRATIONS.

MONDAY, March 23rd.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Syphilis of the Nervous System (3): Dr. Adie.

TUESDAY, March 24th.—2 P.M., Out-patient Clinic: Dr. Adie. 3.30 P.M., Disseminated Sclerosis: Dr. Birley.

THURSDAY, March 26th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Cerebellar Disease: Dr. Gordon Holmes.

FRIDAY, March 27th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Demonstration of Physical Exercises in Exercise Room: Mr. Elmquist.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE PATHOLOGY OF THE NERVOUS SYSTEM.

THURSDAY, March 26th.—12 noon, Inflammatory Reactions in the Central Nervous System: Dr. J. G. Greenfield.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM.

MONDAY, March 23rd.—12 noon, Reflexes: Dr. Hinds Howell.

A COURSE OF CLINICAL DEMONSTRATIONS, chiefly on METHODS OF EXAMINATION OF THE NERVOUS SYSTEM, is held in the Wards at 10 A.M. on Tuesdays and Fridays by Dr. H. J. Macbride.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE NEUROLOGY OF THE EYES.

WEDNESDAY, March 25th.—3.30 P.M., The Oculomotor Nerves.

WEDNESDAY, April 1st and 8th: The Trigeminal Nerve: Mr. Leslie Paton.

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M. or at such other times as may be announced. Full particulars on application to

J. G. GREENFIELD, Dean of Medical School.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, March 20th.—4 P.M., Mr. Nicol Rankin: Nasal Sinus Suppuration.

HOSPITAL FOR SICK CHILDREN, Gt. Ormond-st., W.C.
THURSDAY, March 26th.—4 P.M., Mr. Addison: Cleft Palate.

MANCHESTER ROYAL INFIRMARY.

TUESDAY, March 24th.—4.15 P.M., Dr. C. H. Melland: Drugs of Power.

FRIDAY.—4.15 P.M., Dr. J. C. Bramwell: Electrocardiographic Demonstration. Mr. P. R. Wrigley: Surgical Demonstration.

THE PEOPLE'S LEAGUE OF HEALTH.

Lectures on What We Should Eat and Why, at the Medical Society of London, 11, Chandos-street, W.

WEDNESDAY, March 25th.—6 P.M., Prof. W. E. Dixon: Food Preservation and Adulteration.

Appointments.

ELLIS, H., M.B., B.S. Lond., D.P.H., has been appointed Assistant Medical Officer of Health for Ealing.

RAE, HARRY J., M.B., Ch.B. Aberd., D.P.H., Chief Medical Officer of Health for Aberdeenshire.

TURNER, ADAM A., M.B., Ch.B. Aberd., D.P.H., Medical Officer of Health for Finchley.

Salford Royal Hospital: McCREA, E. D'ARCY, M.B., B.Ch. Dub., Surgical Registrar; STOUT, A. J., M.B., Ch.B. Edin., House Surgeon; WARBURTON, EDWARD, M.R.C.S., L.R.C.P. Lond., Casualty House Surgeon.

Certifying Surgeons under the Factory and Workshop Acts: TIDCOMBE, F. S., M.R.C.S., L.R.C.P. Lond. (Bognor); BARNES, R. G., L.R.C.P. & S. Edin., L.R.F.P.S. Glasg. (Tenterden).

Vacancies.

For further information refer to the advertisement columns.

Belfast, Mater Infirmorum Hospital.—Hon. Asst. Gynaecologist. Belgrave Hospital for Children, Clapham-road, S.W.—H.P., H.S., and Asst. H.P. at rate of £100.

Benenden, Kent, National Sanatorium.—Res. Asst. M.O. £300. Board of Education.—M.O. £600.

Bristol University.—Lecturer in Physiology.

British Guiana.—Asst. M.O.H. £500.

British Hospital for Mental Disorders, 72, Camden-road, N.W.—Hon. P.

Bromley Borough.—M.O.H. £800.

Cardiff City.—Two Asst. M.O.'s. Each £600.

Evelina Hospital for Children, Southwark, S.E.—H.S. at rate of £120. Also Anaesthetist. 25 guineas.

Exeter, Royal Devon and Exeter Hospital.—Asst. H.S. at rate of £150.

Folkestone, Royal Victoria Hospital.—R.M.O. at rate of £150.

Glasgow, Consumption Sanatoria of Scotland, Bridge of Weir.—Res. M.O. £200—£250.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S., H.P., and Asst. Cas. O. Each at rate of £50.

Hull Royal Infirmary.—Asst. H.S. £150.

Hull and Goole Port Sanitary Authority.—Asst. M.O.H. £750.

Leeds City.—Asst. M.O.H. for Maternity and Child Welfare. £600.

Leicester Royal Infirmary.—H.S. at rate of £125.

Liverpool County Borough, Local Education Authority.—Three Jun. Asst. School M.O.'s. £800.

Liverpool, Mill Road Infirmary.—Res. Asst. M.O. £200.

Liverpool Sanatorium, Delamere Forest, Frodsham.—Asst. M.O. £200.

London Homoeopathic Hospital, Great Ormond-street, W.C.—Third Anaesthetist. £50.

London Lock Hospital, 91, Dean-street, W.—Surg. Reg. £100.

Maidstone, West Kent General Hospital.—H.S. at rate of £220.

Middlesex Hospital Medical School.—University Chair of Biochemistry. £800.

Ministry of Health, Whitehall, S.W.—M.O.'s. £800.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Res. Appts. Each at rate of £50.

Paddington Green Children's Hospital, W.—H.P. and H.S. Each at rate of £150.

Prince of Wales's General Hospital, Tottenham, N.—H.S., Spec. H.S., H.P. Each at rate of £150. Also Jun. H.S. and Jun. H.P. Each at £110.

Putney Hospital, Lower Common, Putney, S.W.—R.M.O. £150.

Queen Mary's Hospital for the East End, Stratford, E.—Hon. Asst. P.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—R.M.O. £200. H.S. at rate of £100.

Redhill, Surrey, Royal Earlswood Institution.—Jun. Asst. M.O. at rate of £250.

Rochdale Infirmary and Dispensary.—Jun. H.S. £200.

Royal Chest Hospital, City-road, E.C.—Phys.

St. Pancras Dispensary, 39, Oakley-square, N.W.—Hon. Phys.

Shrewsbury, Royal Salop Infirmary.—H.S. £250. L.P. at rate of £160.

Suva, Fiji.—Port. M.O. and Bacteriologist, &c. £750.

Wallasey, Victoria Central Hospital.—Hon. Asst. Ophth. S.

West African Medical Staff.—Medical Officers.

Births, Marriages, and Deaths.

BIRTHS.

LEWIS.—On March 7th, to Dr. and Mrs. R. T. Lewis, 124, Fellows-road, Hampstead, N.W. 3—a daughter.

MACLAUGHLIN.—On March 13th, at Kensington Court, W., the wife of Colonel A. M. MacLaughlin, M.B., C.B.E., R.A.M.C., Res. Offs., of a daughter.

QUINTON.—On March 9th, at 99, Tollington Park, N. 4., the wife of Percival G. Quinton, M.D., of a daughter.

RICHARDSON.—On March 10th, at Leicester-road, Loughborough, the wife of C. G. Richardson, M.D., F.R.C.S., of a son.

RIDOUT.—On March 14th, at St. Elmo, Southsea, the wife of C. A. Scott Ridout, M.S., F.R.C.S., of a son.

SHELDON.—On March 12th, at Albert-road, Southport, the wife of Harold Sheldon, M.D., of a daughter.

MARRIAGES.

FAIRLEY—PLEWS.—On March 11th, at Christ Church, Burbage, Buxton, Keith Douglas Fairley, M.D., M.R.C.P., to Eileen, elder daughter of Mr. and Mrs. Leonard Plevs, of Buxton.

DEATHS.

ALLWORTH.—On March 13th, at Parliament House, Peckham-road, Alfred Allworth, M.D., L.D.S., aged 87.

CASTLE.—On March 11th, Richard Field Castle, M.B., B.Ch. Camb., of Thornhill House, Darfield, Yorks, aged 64 years.

KIRBY.—On March 14th, at his residence, Kilden, Sutton Court-road, Chiswick, after a short illness, William Egmont Kirby, M.D.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

SUNDERLAND ROYAL INFIRMARY.—This hospital is so crowded, and so many patients are awaiting admission, that the first portion of large extensions is being put in hand. The new block now begun will provide 78 additional beds, which will increase the total number to 318. The Nurses' Pension Fund is in danger of exhaustion. The only remaining investment represents £1050, and the fund is overdrawn.

LEEDS WORKPEOPLE'S HOSPITAL FUND.—At the thirty-eighth annual meeting the Executive Committee of the Leeds Workpeople's Fund presented a record report; the striking feature being that the workshop collections amounted to over £30,000 out of a total income of £40,086—the largest amount ever collected in one year and exceeding by over £3000 the amount collected last year. From the total amount, £20,000 was allocated to the Leeds General Infirmary, £3000 to the Leeds Public Dispensary, £2500 to the Hospital for Women and Children, £1000 to the Maternity Hospital, and to other and smaller hospitals grants in proportion were made. In 1916 the amount granted to the Leeds Infirmary was £5000 and the total grants were £7775.

BRIGHTON AND HOVE PROVIDENT DENTAL HOSPITAL.—The growing recognition by the public of the need for proper dental care was marked by the enormous increase in the number of attendances at this institution during 1924, the report submitted at the annual meeting on March 5th showing an increase of nearly 2000—4802, as against 2807 in 1923. One of the causes of this large increase, it was explained at the meeting, was the greater number of patients under the Sussex Provident Scheme, from which the institution received £117 as against £57 in the previous year. The finances for 1924 showed an excess of income over expenditure amounting to £21 8s. 5d. Colonel Norman C. King, Registrar of the Dental Board of the United Kingdom, presided over the meeting.

MANCHESTER CANCER CAMPAIGN.—Dr. R. Veitch Clark, medical officer of health, has been elected chairman of the Cancer Committee on which, amongst other bodies represented, are representatives of the Health Committee of the city, University of Manchester, Radium Institute, Royal Infirmary, Union Infirmary, St. Mary's Hospital, Ancoats Infirmary, Skin, Northern, and Jewish Hospitals. Arrangements were made for the election of subcommittees comprising men and women specially qualified to deal with the problem. The committee has the approval of the Ministry of Health, who recommend that various questions arising out of a cancer campaign should be periodically reviewed. These questions refer to improved facilities for clinical consultations and pathological examinations, and for cancer treatment (operative, or with X ray and radium apparatus). The adequacy of arrangements at hospitals and institutions serving the area, and for transport of patients, should also be inquired into, and arrangements made for post-graduate demonstrations for the use alike of medical men practising in the area and of the public.

Notes, Comments, and Abstracts.

CHILD LABOUR IN CHINA.

NEWS from China chiefly tells of civil war and opium, and it is not widely known that within the last 20 years Shanghai, the chief port for overseas trade with North China, has become a great industrial centre. Factories with modern machinery have been able to draw their labour from a people of whom millions are always living on the border-line of want, and the Chinese guild system, which was a fairly efficient defence against the worst effects of economic stress among such a population, has failed to adapt itself to the new order. In the absence of any control there has developed a system in which modern machinery exists alongside conditions like those of the early nineteenth century, without the legislative enactments which are an essential part of Western industrial civilisation. Shanghai is an international settlement governed by an elected Council in which the British predominate, every non-Chinese citizen being subject to the jurisdiction of his own consular court, whilst the Chinese are provided for by a mixed court in which a native magistrate sits with a foreign assessor appointed by the consuls. The Council has strictly limited powers of making regulations for the government of the settlement, and under these conditions carries on the government of some 20,000 foreigners and 750,000 Chinese. Perturbed by the state of industrial conditions, the Council appointed a Child Labour Commission, on which they were fortunate to obtain the services of Dame Adelaide Anderson, formerly H.B.M. Principal Lady Inspector of Factories. The report¹ of this Commission has attracted notice in this country and describes conditions which raise again the question how much other peoples are benefited by the adoption of Western ways. In a match factory "young children, certainly not more than five years of age, were to be seen working with almost incredible rapidity." In silk filatures children work, standing, for 12-hour shifts, with not more than an hour off for a meal, and a new form of occupational neurosis is indicated in "a peculiar and rapid up-and-down movement of the body by means of alternately relaxing and then straightening their knees."

Describing conditions during the night shift, the report says: "Rows of baskets containing babies and children, sleeping or awake as the case may be, lie placed between the rapidly moving and noisy machinery. Young children who are supposed to be working, but who have been overcome by fatigue or have taken advantage of the absence of adequate supervision, lie asleep in every corner, some in the open, others hidden in baskets under a covering of raw cotton." Sanitary arrangements are bad and accidents are frequent, whilst the extent of this child labour is shown in a statistical appendix, from which we learn that over 18,000 children under 12 years of age are employed in factories in Shanghai or its immediate neighbourhood. Those factories outside the settlement are of course under Chinese jurisdiction, and there will obviously be trouble if regulations are applied only to those within the limits of municipal authority. The difficulties of the situation are increased by the various nationalities of the owners of the factories—Chinese, Japanese, British, American, French, Italian, and Portuguese. Shanghai people are proud of their city and rightly look upon their international republic as a model from which the Chinese may learn what is best in Western methods of government. The report of this Commission, with its candour in statement and care in considering possible means of action, is an excellent piece of work, and gives assurance that both determination and administrative ability will be applied to the amelioration of the conditions it describes.

SPA TREATMENT IN THE BRITISH ISLES.

IN these columns last year a plea was entered for a comprehensive and national policy in regard to British spas which should, in the opinion of some, supply most of the requirements of British patients. Efforts are being made in many directions to develop on scientific lines the resources for treatment which can be obtained within the borders of our shores. Much good work in this direction has been done by the British Spa Federation, which now includes nine leading spas, all of which comply with a certain standard, while the courses on medical hydrology which are held annually at the London University give facilities for the systematic training of hydrologist practitioners. The third of these courses will take place during the week beginning April 27th and will include a study tour of Buxton.

¹ Reprinted by the Industrial Committee of the National Christian Council, 23, Yuen Ming Yuen Road, Shanghai, China, 1924.

In this connexion we congratulate our contemporary the *Prescriber* on having devoted its March issue to the subject of spa treatment, to which Dr. Fortescue Fox supplies a foreword expressing the conviction, based on "a rather long experience of the spas of many countries," that one especial characteristic belongs to the spas of Great Britain in that they are far more invigorating than continental spas. "Their season," he says, "coincides with the holiday time of our working classes—the manual and intellectual labourers. Indeed, the chief *raison d'être* of the British spas is, or should be, to provide a pleasant retreat and invigorating cure for jaded and failing workers." This number of the *Prescriber* is well illustrated, and the articles include notes on old-time bathing at Bath, on treatment by radio-active springs, on the brine treatment at Droitwich, and on the chemistry of the Buxton and Harrogate waters. There is also a descriptive list of spas in Great Britain, Ireland, and New Zealand.

HEALTH CONDITIONS IN HAMPSTEAD.

DURING a local health campaign in 1923 Dr. Frank E. Scrase, medical officer of health for the borough of Hampstead, read a paper on the Health of Hampstead, Past and Present which has just been published in booklet form following a special resolution of the borough council. A popular and intelligent interest in matters of public health is essential if the campaign against disease is to attain any measure of success, and this publication should certainly help in stimulating such interest. Dr. Charles F. J. Lord, the first medical officer of health for Hampstead, used to complain that he could not make an annual report interesting unless an epidemic occurred, but happily the modern health officer is able to make interesting reading out of a decrease in mortality-rates, as Dr. Scrase has done. After tracing the history of health in Hampstead he goes on to show that the borough can boast a death-rate which is lower than that for England and Wales as a whole, and considerably lower than that for London. The death-rates for certain important diseases, excepting that from cancer, all show a satisfactory decrease within recent years. The infantile mortality-rate for 1922 was the eminently satisfactory figure of 56, but Dr. Scrase insists that this may be lowered still further by attention to the two cardinal principles of breast-feeding and pre-maternity supervision. In the report for the year 1858 Dr. Lord referred to the numerous houses and courts which required thorough eradication: he wrote then "a devastating fire would finally prove a blessing to the parish." Dr. Scrase points out that some of the premises which called for this drastic opinion still exist and still want wiping out. The density of population for the Kilburn Ward is above the average for London, and overcrowding in certain districts is still appallingly prevalent, so that despite the record for health which Hampstead has attained there still remains plenty of work to be done. A child born in Hampstead to-day can expect 12 more years of life than its grandparents: with further progress along enlightened lines the child of two generations hence may quite well be able to boast as much.

HYGROMETRIC TABLES.

THE Meteorological Office has prepared a set of hygrometric tables¹ computed on the basis of Regnault's formula to replace those, prepared by the late James Glaisher, F.R.S., which have been in use hitherto in this country. Tables based on Regnault's formula are already in general use in other countries; this formula, unlike Glaisher's, can be supported by physical reasoning. The new tables are arranged for temperatures in Fahrenheit degrees and vapour pressures in millibars, and they have been computed for a mean atmospheric pressure of 1000 millibars. They are conveniently arranged to give as rapidly as possible the relative humidities, the vapour pressures, and the dew points corresponding with a given range of temperatures of the dry bulb and of "depressions of the wet bulb," the thermometers being exposed in Stevenson screens. The tables are not suitable for use with thermometers exposed indoors—e.g., in factories or storerooms—unless precautions are taken to secure adequate motion of the air over the thermometers by fanning or otherwise. Systematic errors may also be introduced by the use of the tables in climates where the air is hot and dry and calms are of frequent occurrence. In this country, of course, a "calm" rarely prevails inside a Stevenson screen freely exposed; under all atmospheric conditions, even on occasions of strong wind in the open because of the nature of the screen, the velocity of the air past the bulbs in the screen is likely to be of the order of that comprised in the group "light airs." It is for such

¹ Hygrometric Tables for the Computation of Relative Humidity, Vapour Pressure, and Dew Point from Readings of Dry and Wet Bulb Thermometers Exposed in Stevenson Screens. (M.O. 265.) H.M. Stationery Office. 1s. 6d.

conditions as are prevalent in the Stevenson screen in this country that the tables are compiled. It is obviously advantageous to employ tables giving results which agree closely with those prevailing in other countries and are, at the same time, founded on the most accurate reasoning. The tables will be brought into use for the preparation of data for publication from the Meteorological Office as from Jan. 1st, 1925.

BRITISH PRESTIGE ABROAD.

UNDER this title Messrs. Cubitt's Engineering Co., Ltd. (55 and 56, Pall Mall, London S.W.1), announce their intention in a communication to THE LANCET of supplying a certain number of copies of a recent book by Dr. E. Halford Ross, entitled "To Venice and Back in a Two-Seater," at the reduced price of 3s. per copy, postage paid. They hope that other British manufacturers will follow the example of issuing similar propaganda, either by circulating this book or in other ways, the idea being that owners of British cars would thus be encouraged to tour abroad and maintain British prestige. There is something arguable here, but the intention is excellent.

THE PROVISION OF SURGICAL APPLIANCES FOR THE POOR.

THE Surgical Supply Depot at 23, Upper Phillimore-place, Kensington, London, W. 8, is an institution which exists to provide approved surgical appliances at cost price or less to those who require such and whose purses are shallow. The work is not carried on for profit, most of the workers are unpaid, and the depot is supported by voluntary contributions. The depot originated as the Kensington War Hospitals Supply Depot, and during the war it was of great value to hospitals and surgeons. The management are eager to enlarge the scope of their activities and would welcome the co-operation and interest of medical men and nurses all over the country. Anyone desiring to see the depot and how the work is done there will be welcomed, or an illustrated catalogue will be sent free on application. All communications and inquiries should be addressed to the hon. secretaries.

CATALOGUE OF WIRELESS APPARATUS.

WE have received from Messrs. A. J. Stevens and Co., Ltd., Walsall-street, Wolverhampton, a catalogue of wireless receiving sets, valves, condensers, wireless masts, head-phones, and so forth. What appears to be a useful piece of apparatus is the Patent Rejector Circuit, price £2 5s., by which it is claimed the near-by stations, however close, can be cut out and any other station tuned in at will. The price of the receiving sets vary from £17 to 50 guineas and they are made in handsomely finished cabinets. Broadcasting is being more and more used in hospitals and nursing homes as a means of entertaining patients, and some of the apparatus in the catalogue are suitable for hospital as well as for private use.

COLONIAL HEALTH REPORTS.

JAMAICA.

IN the report for 1923, signed by Colonel the Hon. H. Bryan, C.M.G., D.S.O., Colonial Secretary, it is stated that the estimated population of Jamaica at the close of the year was 894,576. 3384 marriages were registered during the year, the rate being 3.8 per 1000 of population. In the same period 34,077 births were registered, of which 17,315 were boys and 16,762 were girls. The birth-rate works out at 38.2 per 1000, as against 37.3 during 1922. 20,278 deaths were registered, of which 10,061 were males and 10,217 females, the death-rate being 22.7 per 1000, as compared with 22.9 in the previous year. 7308, or 36.0 of the total deaths, were those of children under 2 years of age; and of these 5839 were those of children under 1 year of age. The principal causes of deaths (per 1000 of total deaths) amongst the inhabitants of Kingston, the capital, were: Diarrhoea and enteritis, 9.4; atrophy, icterus, and scleroma of the new-born, 11.3; phthisis, 9.5; enteric fever, 6.0; pneumonia, 5.1; heart disease, 6.9; chronic Bright's disease, 3.6; cerebral hæmorrhage, apoplexy, 4.6. The Rockefeller Foundation continued their campaign with a view to the eradication of hookworm in the island. On the withdrawal in 1926 from the colony of the Foundation, the Central Government propose to carry on the campaign for treatment. The parochial boards have recognised the advantages that are derived from sanitation preparatory to treatment for hookworm, and provision of latrine accommodation on approved lines must have the most beneficial results on the health of the colony generally. Arrangements have been made for the appointment of full-time medical officers of health for the parishes of Clarendon and St. Andrew, and a junior sanitary medical officer was appointed during the year under review, who will supervise the sanitary

work in the western part of the island. Alastrim still exists in some of the parishes, and general vaccination continues to be carried out extensively. The campaign against yaws is progressing most satisfactorily. Treatment of venereal disease is receiving attention and a special clinic has been established in Kingston. Notifications of typhoid fever have shown a progressive diminution since 1921. The mean island rainfall for the year 1923 was 57.45 inches, showing a large deficiency when compared with the 50-year average of 76.46 inches. In Kingston the mean temperature for the 12 months was 79.2°, the average for 33 years having been 78.7°. Slight earthquake shocks were reported in January, June, July, August, September, and December, but none during the other months.

UGANDA.

The population of this Protectorate on Dec. 31st, 1923, was estimated to be 3,127,455, composed of 1289 Europeans, 6521 Asiatics, and 3,119,645 native inhabitants. The territories comprised in the Protectorate lie between the Belgian Congo, the Anglo-Egyptian Sudan, Kenya, and Tanganyika. Uganda is flanked on the east by the natural boundaries of Lake Rudolf, the river Turkwel, Mount Elgon (14,200 feet), and the Sio River, running into the north-eastern waters of Lake Victoria, whilst the outstanding features on the western side are the Nile watershed, Lake Albert, the river Semliki, and the Ruwenzori range (16,794 feet), and Lake Edward. The annual report states that the health of the natives, both bodily and mental, is receiving closer attention; immense strides have been made in affording better facilities for medical treatment, and in so far as education is concerned a comprehensive scheme has now been devised supplementing work at present carried out by missionary societies. Vital statistics for Buganda and the neighbouring Bantu districts record an excess of births over deaths, although in Buganda and Bunyoro the number of deaths exceeds the births. The figures for the year 1923 show that satisfactory progress has been made in reducing the proportion of still-births. Wide expansion has taken place in the treatment of native diseases, particularly venereal diseases. With a view to bringing medical treatment within the reach of natives throughout the Protectorate a system of sub-dispensaries in charge of trained native attendants is being established. Those already established, numbering 27, have proved at once successful and popular with the natives. A total of 184,601 cases received medical treatment, as compared with 116,600 cases in 1922. During the year 74 cases of black-water fever occurred, 17 of which were fatal, the corresponding figures for 1922 being 83 and 14 respectively.

The climate of the Protectorate as a whole, though pleasant, cannot be considered healthy for Europeans. European children as a rule thrive in infancy, but considerable risk is attached to bringing them out when they are over 2 or 3 years old, as they are liable to attacks of malaria and the resultant anæmia. The health of adults depends mainly on their mode of life; with care constitutional health should not be impaired, but if physical fitness is maintained the altitude and proximity to the Equator combine to produce nervous strain after prolonged residence. Outdoor manual labour is dangerous for Europeans, and on plantations a manager's or owner's duties are for the most part supervisory. The mean maximum temperature for most districts averages 80° F. and the mean minimum 60°. On the Ruwenzori range there is extreme cold with perpetual snow, and it is also cold on the higher slopes of Mount Elgon. In the Nile valley, near Lake Albert, on the other hand, the mean maximum temperature is 90° and the mean minimum 74°. The favourite localities for European plantations are the Buganda Province (particularly the Mengo and Mubendi districts), the Toro district of the Western Province, and the Bunyoro district of the Northern Province. There are a few estates in Busoga (Eastern Province), but this is not so popular. The rainfall at Entebbe during 1923 amounted to 89.04 inches distributed over 160 days—the highest rainfall recorded in the Protectorate. Two main rainy seasons are anticipated annually. The first, the "long" rains, usually begin in March and may continue through June; the second, or "short" rains, in September and extend through October and occasionally November. Much of the rain falls during the night or early morning. Violent thunderstorms and heavy showers occur frequently in the daytime, but these are only of local incidence.

NOTTINGHAM HOSPITALS. — During the next 18 months Nottingham General Hospital will be greatly extended at a cost of £72,000.—The Nottingham and Midland Eye Infirmary is in the unusual position of having money in hand but a deficiency of patients, and the chairman of the committee at the annual meeting of the governors appealed for an increase in the number.

Goulstonian Lectures

ON THE STUDY OF

GASTRIC FUNCTION IN HEALTH AND DISEASE.

By JOHN A. RYLE, M.D., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN AND LECTURER ON MEDICAL PATHOLOGY,
GUY'S HOSPITAL.

LECTURE II.*

IN the introductory chapter to his Lectures on Diseases of the Stomach, Brinton,¹ discussing symptomatology, writes as follows:—

"In short, the stomach is devoid of all common sensibility. But we are not therefore to imagine this important organ really insensible to stimulation; or to suppose that, because it is not every moment arousing the brain of its master, and demanding his forethought or exertion, it remains unimpressed and inactive. On the contrary, we must rather conclude that it has a special sensibility of its own; not one whit less marvellous (but surely more so) for possessing a certain independence of the cerebro-spinal centre. Closely related to this centre by the feelings of hunger and satiety—nay more, dictating to it (so to speak) those exertions which the proper alternation of these two states imperiously demand from the mass of mankind—it has a sphere of action altogether its own. And the study of digestion has shown us how admirably and silently the stomach fulfils its various and complex tasks; and how, incidentally to these, the unfelt particle of food no sooner touches its mucous surface than it excites the flow of a variety of secretions, both far and near, and provokes movements in the muscular substance of its walls and vessels, as well as in the analogous structures of neighbouring parts. To these acts, which respectively constitute the sensation and motion of the healthy stomach, its morbid states afford an instructive parallel. And just as the kind of sensibility specific to a healthy muscle—the feeling of its strength, its equilibrium, its measurable force—seems to be traceable, by gradual modifications through healthy fatigue to the feverish soreness of over-exertion, and through this to the universal muscular pain and prostration of various grave general ailments, so the indistinct sensation of the healthy stomach affords us the best clue to the acute sensibility of the diseased one; and allows us to trace a scale of similar kind—from satiety to repletion; from repletion to distension and weight in the epigastrium; and from hence to the dull heavy aching of dyspepsia, the gnawing or burning pain of ulcer, and the sharp agony of cancer of the stomach."

The latter portion of this passage was appropriately quoted by Hurst in his Goulstonian lectures on the Sensibility of the Alimentary Canal. I cannot refrain from quoting again the fuller passage, for in writing thus it seems to me that Brinton, with his clear perception and reasoning, anticipates the results of those later scientific inquiries to which I have already referred. He recognises that the muscle of the stomach, rather than its mucosa or its glandular structures, is the element principally responsible, not only for the proper performance of its digestive functions, but also for the appreciation of its states of comfort and discomfort. And at the same time he reminds us of the importance of endeavouring always to trace the gradations between states which can respectively be classified as physiological and pathological. However correct or otherwise it may be to introduce the analogy of skeletal muscle in discussing the functions of the plain muscle of the stomach, there can be little dispute as to the practical utility of that analogy. For just as I have in my first lecture pointed to the association of good appetite and healthy tonus with general well-being and muscular fitness, so, too, in reviewing symptoms we may correlate general hypersthenic and hyposthenic states with gastric hypersthenia and hyposthenia. Further, in the case of more local gastric

disease we may frequently ascribe with reason certain pains and discomforts to fatigue, exhaustion, or over-activity of the muscle-fibre. The natural discomforts of hunger induced by fasting and attributable, as Carlson² has shown, to increased tonic and peristaltic activity may be traced through various morbid discomforts to the unmistakable hunger-pain of visceral disease. If a "sinking sensation" relievable by food is developed with unusual readiness it will commonly be found that the patient has a hypertonic and rapidly emptying organ. This symptom has been described by Hurst³ as occurring in the healthy members of families with a tendency to duodenal ulcer, and in further support of his views on the "ulcer diathesis" he has described families in which several members actually developed proved duodenal ulceration. In my own practice I have encountered similar families. In the early phases of a chronic duodenal ulcer patients may describe sinking sensations before they develop actual hunger-pain, and between the sinking sensation and the hunger-pain is an intermediate type of discomfort sometimes referred to as a sense of local "pressure" in the epigastrium. In a comparable way the pain of angina pectoris is often preceded by a sensation of retrosternal pressure or oppression, and it is of interest that the early discomforts both of angina and duodenal ulcer are commonly mistaken for flatulence by the patient.

If, instead of a sinking sensation before meals a sensation of fullness or repletion or weight after meals is too readily acquired, it will not uncommonly be found that the total capacity of the stomach has been diminished by structural disease, or (more rarely) by extreme hypertonus; that its emptying rate has been hampered by a narrowed outlet; or that its power of adaptability has been reduced by a loss of tone. The decision as to which of these divergent causes is likely to be responsible in an individual case must, of course, depend on an analysis of other elements in the anamnesis or the physical examination. Thus a good appetite in association with a rapidly developed sense of fullness after food suggests a small hypertonic organ. A much impaired appetite with a rapidly developed sense of fullness more probably points to grave structural disease of the stomach wall when the leading symptoms are of a local kind, or to hypotonus in states of general ill-health.

When it is stated that gastric pain originates in the muscle-fibre and reflects an exaggeration of the same factors which call forth appetite, hunger, and repletion, it should be clearly understood that reference is only made to the gastric *visceral* pain. It would be impossible in the time at my disposal to consider in detail the theories of Lennander⁴ who demonstrated the insensibility of the viscera to ordinary stimuli, and of the late Sir James Mackenzie,⁵ who for this and other reasons held that pain does not originate in the viscera, but is referred to the somatic tissues; or to the contentions of Ross,⁶ Hurst,⁷ and others, who have regarded visceral pain and referred pain as distinct phenomena. The latter view is now the more widely accepted, and of its probable truth we have daily reminders. Most careful observers, including members of our own profession, who have experienced severe visceral pain, locate it at a point deep to the body wall, and when confusion by the coexistence of referred pains or other distracting symptoms is not too great, their localisation is usually remarkably accurate. Furthermore, if normal sensations such as hunger or the desire to micturate are produced in the viscera—and I have not seen it urged that these sensations too are referred to the somatic tissues—it would at least seem reasonable to suppose that abnormal sensations must also have a local origin. During the past few years I have constantly registered observations relating to reflex phenomena in disease of the abdominal viscera, testing for the presence of cutaneous and muscular signs as a routine in almost every abdominal examination I have made.

* Lecture I. appeared in THE LANCET last week, and Lecture III. will appear in a subsequent issue.

As a result of these observations I have concluded that indisputable viscerosensory and visceromotor signs persisting apart from a severe visceral crisis invariably point to the existence of an inflammatory or ulcerative lesion. I have not found such signs as cutaneous soreness and muscular guarding present in the gastric zone of reference in cases of gastric pain due to remote causes. During the healing of gastric and duodenal ulcers I have carefully watched the disappearance of these reflex signs, and I have not found them present in such conditions as pyloric stenosis, in which there was good reason to suppose that the active ulcer had been replaced by a scar. Conversely, the deeper the ulcer the more constantly have I found the signs to be present. Although they may be exaggerated or brought to light by a crisis of visceral pain these reflex signs may persist quite apart from the pain; indeed, in ulcer they may be present for days or even weeks after the disappearance of all spontaneous pain. In other words, the somatic phenomena of visceral disease are an expression not of the visceral pain but of the lesion, which, also by reflex mechanisms, causes the visceral pain. When visceral pain is due to mechanical causes, or occurs independently of a lesion, as in ordinary colic, or in response to some distant stimulus, as in appendicular dyspepsia, then there are no associated viscerosensory or visceromotor symptoms in the somatic zone served by the segment of the cord supplying the painful organ. The same observations have been confirmed in the case of other hollow viscera.

I have made this digression merely to emphasise my belief that gastric pain and the referred pains of gastric disease are separate manifestations and that the latter are not a mere reflection of the former.

Gastric pains may, as has long been recognised, be broadly classified into those which develop shortly after taking food and those which develop after a much longer interval, when the stomach is again becoming empty. These will be referred to respectively as "immediate" and "delayed" pain. Gastric pain persisting apart altogether from the act of eating can generally be traced to extragastric causes or to an extension of gastric disease beyond its seat of origin. Similarly, precordial or retrosternal pains persisting apart from effort or emotion are usually extracardiac in origin. In other words, visceral pain has a definite relationship to visceral function and expresses perverted activity rather than structural disease. In clinical work so much depends on a proper appreciation of the nature and causes of a particular pain that it would seem desirable, notwithstanding the frequent discussions which have been devoted to this subject, to attempt once more an analysis of the two main types of gastric pain.

No lesion more clearly demands consideration of the causes of the pain associated with it than peptic ulcer. In gastric ulcer we have an example of "immediate pain," arriving rapidly after eating, and in duodenal ulcer we have an example of "delayed pain." In both conditions (though with less constancy in gastric ulcer) there is a definition about the pain and about its localisation and associated symptoms which render it peculiarly amenable to study.

Originally it was supposed that the pain of peptic ulcer was due to irritation of the ulcer itself by the physical contact of food or the chemical irritation of the gastric hydrochloric acid, the relief afforded by alkalis supporting the latter view. The first view is made improbable by the observation originally due to Hurst⁷ that although food starts to enter the duodenum shortly after its ingestion the pain in duodenal ulcer does not develop until the stomach is nearly empty; furthermore, if friction were its essential cause, the pain would surely be more continuous from simple contact of the ulcer with the opposite wall of the empty viscus. That the pain is not due to the acid was also shown by Hurst,⁷ who failed

to produce it in several cases of gastric ulcer by the introduction into the stomach of 4 oz. of a 0.5 per cent. solution of hydrochloric acid.

Hurst concluded that gastric pain is an expression of hypertonus, excessive peristalsis and inhibition of pyloric relaxation—all factors liable to increase intragastric tension and tension in the muscle-fibre. In the case of ulcers near the pylorus he suggested that actual pylorospasm analogous to the anal spasm accompanying anal fissure might be an additional factor. He considered, however, that acid might indirectly cause the pain by promoting muscular action and preventing relaxation of the pylorus. Personally, I am doubtful whether it is necessary to introduce the acid factor at all. I have myself examined many cases of gastric ulcer, with extreme degrees of hypochlorhydria and a few with complete achlorhydria, in all of which the pain was just as severe and characteristic as in cases associated with a normal or high acidity. Given an irritative focus, the ingestion of food, or the readiness for it, even in the absence of acid secretion, is an adequate stimulus for the initiation of the exaggerated tonic and peristaltic action upon which the pain depends. Reasons will be given later for supposing that the relief of pain on giving sodium bicarbonate may be due to other factors than the neutralisation of acidity.

"DELAYED PAIN."

Hurst, in his Goulstonian lectures,⁸ states that hunger pain develops when "only a small proportion of the food is still present in the stomach and the hypertonic condition constantly present in cases of duodenal ulcer reaches its greatest development, owing to the increase in tone which occurs as the bulk of the gastric contents diminishes." With this I am in entire agreement. In a more recent review⁹ of the subject, however, he has ascribed the pain of duodenal ulcer to the great increase of pressure in the pyloric vestibule which arises when a peristaltic wave shuts off this portion from the rest of the stomach and food is simultaneously prevented from entering the duodenum by a reflex achalasia (or failure to relax) on the part of the pyloric sphincter. He also argues that the acidity plays a part in maintaining the pyloric achalasia, and that the relief due to food and alkalis is partly caused by diminution of the acidity. The sustained character of the pain, which shows no synchronism with peristaltic movements, does not to my mind accord with this hypothesis; and, further, if achalasia of the sphincter were so complete as to permit of a sustained rise in pressure, there would surely be delayed emptying instead of the normal or rapid emptying commonly present in these cases. M Crea¹⁰ has recently shown that complete separation of the pyloric antrum is a common event in the normal "J"-shaped stomach, but that it does not occur in the normal "steer-horn" stomach, the type with which duodenal ulcer is most commonly associated. I must also disagree with Hurst when he says that increased tension in the gastric muscle-fibre is the adequate stimulus for "the associated reflex symptoms of tenderness and rigidity in the corresponding segment of the rectus abdominis muscle."⁸ The impulses constantly passing from the ulcer itself are the adequate stimulus for these signs, just as they are the adequate stimulus for the exaggerated tension of the gastric muscle-fibre. It is true that the signs may become more definite when spontaneous pain is present—that is to say, when there is increased stimulation of the ulcer—but my own observations, already referred to, have shown again and again that rectus rigidity and cutaneous soreness persist quite apart from the occurrence of spontaneous pain, and are absent in pyloric stenosis from a healed ulcer, a condition in which increased tension of the muscle-fibre must surely exist.

If it should become necessary, in the light of recent observations, to reject altogether the theory of "acid control" the development of a pathological degree of hypertonus in an organ already predisposed

to that condition would still be readily explicable. Carlson¹⁰ has shown that any stimulus to the duodenum tends to produce contraction above; in the presence of duodenal ulceration the intensity of all stimuli is increased and gastric hypertonus and pain occur as soon as the diminution in the bulk of the gastric contents makes this possible. Pain disappears at those times at which relaxation of tonus (or adaptation of posture) develops in response to the introduction of food, fluid, or gas into the stomach. I believe that simple "adaptation of posture" is the essential relieving factor in the case of hunger-pain. Sodium bicarbonate is much more effective than bismuth oxycarbonate in producing relief. May it not be that this is due to the rapid evolution of gas and a more effective relaxation of tonus? Alkalies are less effective in cases and conditions in which achlorhydria has developed and gas is not evolved. Dr. E. P. Poulton and Dr. T. Turner tell me that an even more effective relief of pain in ulcer cases results if an effervescent mixture is given, and that such a mixture is in great demand among their hospital out-patients. The eructations produced by displacement of some of the gastric air-bubble give the sense of relief to the patient, but it is difficult to see why this should be the whole cause of the relief in duodenal ulcer, as any further reduction in content short of complete emptying would tend to increase rather than to lessen tonus. It is, however, probable that the pylorus, working in unison with the pars pylorica, also adapts its posture or relaxes when the gas is evolved and so facilitates emptying. Spencer, Meyer, Rehfuess and Hawk¹¹ have shown that sodium bicarbonate hastens the emptying of the stomach. The fact that relief in duodenal ulcer is also, and often more effectively, obtained with milk, water, whisky and water, or even small quantities of dry food, further suggests that relief of pain by alkalies is not specific but due simply to the adaptation of posture which follows eating or drinking. That the acid alone is not an adequate factor for the production of pain is supported by the observation that the resting acidity in the early morning is often the highest recorded acidity in the day; some of this must escape into the duodenum, but pain in duodenal ulcer does not occur as a rule before breakfast and usually disappears on fasting. For the production of the pain it is necessary to oppose a resistance to the contracted muscle-fibres in the shape of the small quantity of food present in the later phases of digestion, or, in other words, to induce fatigue in it by providing it with "work" at a time when its tonic activity is already exaggerated.

I have recently had under my care a colleague who had a gastro-jejunostomy performed 30 years ago for duodenal ulcer with stenosis. Later, after many vicissitudes, the stoma also became narrowed. In 1922 it was shown to be working inefficiently, and only the merest trace of barium passed out through the pylorus; at the same time he was found to have developed achlorhydria. With the advent of autumnal weather in 1924 he had a return of characteristic hunger-pain, night-pain, and relief by food. Alkalies were much less successful than in the past, but frequent small feeds, rest, and belladonna produced a steady improvement. His case exemplifies three points: (1) With a marked stenosis of the pylorus, which is now almost certainly incapable of contraction or relaxation, he had typical hunger-pain due presumably to general hypertonus of the pars pylorica. (2) The pain occurred in the absence of free acidity. (3) In the absence of free acidity alkalies failed to give the customary relief, not, I believe, because the pylorus was incapable of relaxation, but because with no evolution of gas no adequate relaxation of the pars pylorica was obtained.

We have a further clinical observation suggesting that pain of the type occurring in duodenal ulcer bears no necessary relationship to the acidity. The opportunity of confirming this observation we owe to our surgical colleagues. Briefly, it is that the whole of the subjective syndrome of duodenal ulcer

can be closely and sometimes exactly simulated by disease of the gall-bladder or appendix independently of the chemical response. Many of us must have seen hunger-pain and night-pain and relief by food and alkalies in patients who were subsequently shown to have no gastric or duodenal lesion at all. In other words, the reflex hypertonus of the pars pylorica and pylorus may be induced in a normal stomach by a distant lesion, and although hyperchlorhydria secondary to the pyloric hypertonus is present in a certain proportion of these cases, it is by no means an essential accompaniment, and there may be a complete absence of free acid. Thus I have recently seen a case of chronic appendicular disease with complete achlorhydria in which the patient described pain in the epigastrium and feelings of flatulence coming on two and a half hours after breakfast and immediately relieved by lunch. The pain returned at half-past three and was relieved by tea, and at half-past ten in the evening, dinner having been at half-past seven. These pains were liable to keep the patient awake sometimes until two or three in the morning. I have also seen hunger-pain, night-pain, and relief by food in gastric carcinoma with achlorhydria.

Patients with duodenal ulcer describe their pain, when it arrives, as persistent, although sometimes of a "crescendo" character. It is never described as rhythmical or griping, although Carlson² states that a rhythmical quality can be dissociated from the sustained pain. Gastric "colic" or griping pain is experienced in acute indigestion from unsuitable food and as a preliminary to vomiting when the pylorus is strongly resisting the passage of indigestible fragments. It is seen also in early pyloric stenosis or obstruction, but here again the general hypertonus may tend to the production of a sustained rather than a rhythmical pain. The sustained character of the pain in non-obstructive duodenal ulcer is in favour of the view that it is due to hypertonus, probably involving the longitudinal as well as the circular fibres, rather than to segmentation by an increased peristaltic contraction as Hurst suggests.

In his recent experiments on the control of the pylorus in animals Carlson¹⁰ showed that spasmodic contractions of the pylorus can be induced by injuring various abdominal viscera or by stimulation of the peritoneum, an observation which accords with clinical experience. I have seen the syndrome usually associated with duodenal ulcer closely reproduced by appendicitis; by cholecystitis or gall-stones with cholecystitis; by lesser curvature ulcers (particularly those situated at the pyloric end of the stomach); and more than once by carcinoma ventriculi. In one case the symptoms were simulated by the peripheral irritation of a small fatty protrusion through the linea alba; in another by excessive tobacco smoking. Even worry and overwork at times constitute the adequate stimulus. With a few exceptions my patients were men, and the majority of these were of the broad-chested and hypersthenic type, or lean and nervous. I believe with Hurst that the physiological "habitus" of the stomach is one of the main factors determining the nature of the dyspeptic response, and that on this hypothesis we can best explain the observation that the same symptoms may be evoked by such a variety of stimuli. The hypersthenic habitus is present more constantly in duodenal ulcer than with any other lesion, but when it is present in association with another lesion the same response is produced.

IMMEDIATE PAIN.

The pain due to ulcers of the lesser curvature develops within a quarter or half an hour to one hour of taking food, or sometimes rather later; it is relieved by vomiting, fasting, and alkalies. In a considerable proportion of cases of gastric ulcer the radiologist can demonstrate a spasm of the greater curvature opposite to the ulcer, the so-called "spasmodic hour-glass" appearance. That this spasm in itself is not the whole cause of the pain is obvious from the fact that it is often very persistent, and that

it may be demonstrated when no pain is being experienced. Nevertheless the spasm must be associated with a shortening of muscle-fibres, partly reflex in character, and (in the more chronic cases with deep ulceration) partly attributable to inflammatory changes, or commencing scarring in a group of the circular fibres; some such shortening is probably present in a lesser degree even when the "spasm" is not demonstrable. This shortening prevents or limits normal adaptation of tonus or posture when food is introduced, and therefore tension in the muscle-fibre is further increased and pain results. Getting rid of the food (by fasting or vomiting) is the surest method of relief, and relief by vomiting, whether spontaneous or induced by a finger in the pharynx, is commonly described by patients.

Some experiments reported by Poulton¹² support the foregoing conclusions with regard to pain in gastric and duodenal ulcer. With cases of ulcer of the lesser curvature Poulton found that his patients could obtain relief from their pain by swallowing the gastric tube into the proximal portion of the stomach and allowing an escape of some of its gaseous content. Conversely, by blowing air at known pressures into the stomach he could reproduce their pain. On the other hand, in a case of duodenal ulcer, inflation caused great distension but no pain. I am therefore inclined to think that the administration of sodium bicarbonate produces relief by facilitating belching in ulcers of the lesser curvature, but by causing relaxation of general and pyloric hypertonus in duodenal ulcer.

Just as the pain of duodenal ulcer may be simulated by the reflex effects of distant abdominal disease, so, too, the pain of gastric ulcer may be simulated. In this instance, however, the hypertonus is of a more local character and is referred to the fundic half of the stomach. Hurst¹³ and Langdon Brown¹⁴ have reported visualisation (with the X rays) of a gastric spasm induced by pressure over an inflamed appendix, and the occurrence of epigastric pain on pressure over McBurney's point in "appendicular dyspepsia" is a familiar observation. I have formed the impression that in men there is a greater tendency for duodenal ulcer and in women for gastric ulcer to be simulated by cholecystitis and appendicitis. This again accords with the hypothesis that, whether the focus of irritation be in the stomach, the duodenum, the gall-bladder or elsewhere, the nature of the response in the particular sex or type is commonly determined by the physiological tendencies or gastric habitus of that sex or type. With the hypersthenic habitus the response is "delayed pain"; with the hyposthenic habitus the response is "immediate pain."

In gastric carcinoma the two main factors underlying the production of pain are pyloric obstruction and rigidity of the stomach wall. The first causes pain by preventing evacuation and amplifying the tonus and the depth and number of the peristaltic waves; the second by obviating adaptation of tonus when fluid or food is introduced. In some cases of growth involving the body of the stomach there is remarkably little pain, and in these it may be found that there is a rigidly patent pylorus, and that evacuation is extremely rapid. Needless to say, other and more persistent types of pain develop when the growth has spread beyond the limits of the stomach and has begun to invade neighbouring structures.

The greater our experience of epigastric pains the less inclined are we to be dogmatic in our diagnoses based upon them, for careful investigation and laparotomy are continually revealing our deficiencies. These deficiencies depend partly, no doubt, upon inherent difficulties and our own shortcomings, and partly upon the inadequate powers of observation and description of our patients. Nevertheless, with better appreciation of the causes of visceral pain and the establishment of new methods of clinical inquiry we undoubtedly win by gradual stages to a higher standard of accuracy. In the words of Hilton¹⁵

"every pain has its distinct and pregnant significance if we will but carefully search for it."

When probing the nature of a visceral pain it is as necessary to proceed with method as it is in the conduct of any other physiological experiment. Needless to say, the procedure is much more difficult and exacting than any laboratory exercise, but the information which may be obtained by careful questions from a patient of intelligence is often remarkable, and that the anamnesis is the most necessary part of the clinical inquiry is perhaps better illustrated in the case of the dyspepsias than in any other brand of internal medicine. When we pause to consider the interrogatory in respect of a gastric pain we find that—apart altogether from associated symptoms and referred signs—there are at least nine reasonable questions which may be put. Thus we may inquire as to: (1) The character of the pain; (2) its severity; (3) localisation; (4) extent of diffusion; (5) frequency; (6) duration; (7) initiating factors; (8) aggravating factors; and (9) relieving factors. Reasonable answers to only one-half of these inquiries, but particularly to numbers (1), (2), (3), (8), and (9) will again and again suggest a reasonable diagnosis. But if there is one principle which it is important to observe above all others it is that of endeavouring to see the patient at a time when he is actually experiencing his pain, or even to take steps to reproduce his pain by giving or withholding food. At such times he can more clearly define and locate his symptom, and at such times reflex signs, absent or inconspicuous on other occasions, are likely to be unmasked.

FULLNESS AND DISCOMFORT.

Fullness and discomfort which fall short of actual pain are due to identical mechanisms and depend on similar causes. In addition to local causes general disease and toxic or emotional factors may influence the health or tonus of the muscle-fibre in the direction either of relaxation or exaggerated action, so that we find in tuberculous, neurasthenic, and psychoneurotic patients a frequent complaint of dyspeptic discomforts. These symptoms seldom have the severity or the defined characters of pain due to structural disease or reflexly induced by neighbouring or distant organic lesions. In their time relationship with meals, however, discomforts show the same behaviour as pains, and once more the nature of the response seems partly to be determined by the gastric habitus of the individual.

FLATULENCE.

Epigastric fullness and discomfort lead naturally to a consideration of the familiar symptom of gastric flatulence. In the vast majority of all cases gastric flatulence is due to swallowed atmospheric air. In health small quantities of air are swallowed with the saliva and the food, and the presence of a fundic air-bubble is always demonstrable by percussion and X ray examination. The sensation of flatulence and subsequent eructation can be reproduced in health by voluntarily swallowing air, or by taking an effervescent mixture, and by the gulping of air which involuntarily accompanies a choking fit. As has been mentioned eructations of a minor kind also accompany hunger. The sensation of flatulence is one of pressure or of fullness high up in the epigastrium or under the sternum, or sometimes more widely diffused about the chest; occasionally a pain is referred to the angle of the left scapula. In pathological flatulence the symptom may be produced by the habit of aerophagy or "air-sucking" irrespective of the physiological characters of the stomach. The sensation of flatulence may also be experienced with a normal air content in subjects with gastric hypertonus, and is then identical with the feelings of pressure which precede the development of pain in duodenal ulcer.

The habit of air-swallowing is developed for various reasons. It is a common symptom of anxiety states

and so occurs in the psycho-neurotic patient. I have on several occasions seen it initiated by the swallowing movements which accompany a sore throat or a chronic pharyngeal or naso-pharyngeal catarrh, and in this connexion I believe that a type of catarrh regarded by some laryngologists as secondary to a dyspepsia is often rather the cause of the dyspepsia. I have once developed aerophagy and flatulence myself for a short time after painting my throat with an iodine preparation. The symptoms may follow the administration of a general anæsthetic, particularly ether, in which case, I presume, the gulping movements during induction or the retching during recovery may initiate the discomforts and establish the habit. The soft diet and inefficient mastication necessitated by dental extractions commonly cause flatulence. Of the organic diseases with which the complaint of flatulence is associated duodenal ulcer and still more gall-stones and cholecystitis are the most important. In both there is a tendency to pyloric hypertonus and to feelings of epigastric pressure, sometimes (especially in the presence of gall-stones) of a "bursting character." These local feelings suggest to the patient the presence of an excess of gas in his stomach, and in attempting to eructate he sometimes aggravates the condition by swallowing more air. The retrosternal oppression experienced in angina, being mistaken by the patient for an œsophageal or gastric sensation, also commonly induces aerophagy. In aerophagy, however initiated, relief follows from time to time with an explosive effect when the cardia is forced by the accumulated gas in the fundus. Flatulence from aerophagy is odourless, tasteless, or mingled with the flavour of the food last taken. Gas resulting from diffusion into the stomach, if this occurs, must be very small in amount, and it is difficult to imagine any pathological state which would appreciably modify the rate of such diffusion.

Fermentation of food does not take place in the stomach excepting in association with pyloric delay, for the normal sojourn of the gastric contents is too short and the acid secretions help to inhibit bacterial action. I have never seen active fermentation occurring in the fractional specimens of healthy subjects at room temperature. On three occasions I have seen active fermentation at room temperature in specimens obtained from patients, and in each case the diagnosis was pyloric stenosis or obstruction. Fermentation is said to be more common in obstructive carcinoma because of the absence of free hydrochloric acid, but I have met with it also in pyloric stenosis from cicatrization of an ulcer, and in traumatic stenosis following the swallowing of a caustic alkali; in each instance free acid was shown to be present. Flatulence occurring under these conditions may have the odour of sulphuretted hydrogen, and in any chronic dyspepsia with malodorous eructations organic interference with pyloric function should be suspected and will almost certainly be found. I have recorded the symptom quite as frequently in pyloric stenosis as in cancerous obstruction. In the case of a medical man whom I saw with Dr. A. F. Hurst and Mr. C. H. Fagge, eructation of sulphuretted hydrogen was the first and only prominent symptom of a carcinoma of the pylorus. Operation was performed without delay and the growth resected. The patient lived and remained at full work for more than two years.

ANOREXIA.

Loss of appetite has already been discussed in the process of reviewing the gastric element of the appetite sensation. The main disturbances of motor function accompanying anorexia are diminished tonus, or a pathological rigidity of the stomach wall. In otherwise healthy persons anorexia of a mild grade may result from severe or prolonged fatigue. Fatigue, whatever its pathology may be, is largely a muscular symptom, and the plain muscle of the stomach betrays the state of fatigue by loss of tone and loss of appetite. Profound emotion and prolonged worry

may also impair gastric tonus, probably through the medium of the sympathetic nervous system, but as under these conditions there is often loss of sleep and physical rest, fatigue factors may again be contributory. In neurasthenia, whether due to physical or psychological stresses, or to intoxications, or to some combination of these factors, loss of appetite occurs for reasons similar to those already given. In all these conditions it should be clearly appreciated that there may not be a demonstrable hypotonus, for hypotonus is a relative term, and in a subject with the hypersthenic habitus the development of a normal or average tonus or of a lessened hypertonus may cause symptoms. In acute fevers and in chronic infective illnesses muscular tonus is impaired by the circulating toxins. In mental disease and the anorexia nervosa of Gull, the initial factor may be mental depression or a simple refusal to eat, but at a later stage exhaustion and relaxation of tonus complete the vicious cycle. In chronic alcoholism loss of appetite is probably to be attributed partly to the general effects of the poison on muscular function and metabolism, and partly to the excessive secretion of mucus which inhibits normal stimulation of the gastric mucosa and consequently the appetite stimuli directly due to eating. Beaumont¹⁶ showed that acute alcoholism in the case of Alexis St. Martin might result in superficial lesions of the mucosa with suppression of secretion and stagnation of food, but Alexis did not always experience gastric symptoms or loss of appetite in the presence of these changes. Carlson,² producing alcoholic intoxication in dogs, demonstrated an abolition of tonus and hunger contractions coincident with refusal of food and vomiting. In carcinoma of the stomach, and especially in diffuse carcinoma, anorexia is almost as constant a symptom as pain, and in the absence of a palpable tumour or metastases more surely directs attention to the diagnosis than any other symptom or sign.

The anorexia of fatigue is cured by rest. The toxic anorexias are cured by the withdrawal of the poison. The anorexia of infective states is relieved by the termination of the infection or (as in pulmonary tuberculosis) by improving the patient's response to it. The anorexia of carcinoma ventriculi cannot be relieved, as nothing can restore the tonus of the muscle.

In all the common forms of anorexia, apart from that due to carcinoma ventriculi, in which it becomes continuous, the symptom is observed with curious frequency in the morning. The breakfast appetite is usually poor in the alcoholic and in the exhausted or tuberculous patient. Whether this expresses an incomplete recovery from the fatigue or toxins of the previous day, aggravated perhaps by unrefreshing sleep, or whether under these circumstances the stomach requires the actual ingestion and the stimulant and restorative effects of food before it can register a tonic response, I do not know. Possibly in toxic and fatigue states minor variations in the blood-sugar, upon which the activity of muscle in part depends, may be a factor, for in the early morning the blood-sugar is normally at its lowest level.

EXAGGERATED HUNGER AND BULIMIA.

Exaggeration of hunger and appetite is seen in the early stages of diabetes and sometimes in Graves's disease; later, when a general debility supervenes, it may be replaced by loss of appetite. Bulimia, or an abnormal hunger or craving for food appearing without obvious cause, is generally psychogenic, but it may accompany cerebral tumours. The only records of the symptom in my own case-notes were among the nervous dyspeptics.

NAUSEA.

In speaking of hunger and appetite I have been careful to insist that their gastric elements alone were under review. Other and more general disturbances, including malaise, weakness, sweating, and salivation,

commonly accompany nausea, but few would deny that it includes a local gastric element. In health nausea is induced by disgusting sights, smells, and emotions; is experienced in acute fatigue, and accompanies early pregnancy. Oily and fatty foods and remedies, which are known to inhibit gastric motility and secretion, readily induce it, and more so in persons who have small appetites and hypotonic stomachs, and whose food requirements are low, or in persons with normal food requirements when these requirements are diminished by hot weather. Nausea frequently accompanies feelings of faintness, and Barclay¹⁷ has observed a drop of 3 inches in the lower border of the stomach just before fainting occurred. In another instance "a normal stomach dropped an inch or more when the patient smelt something which, to him, was nauseating. Asafoetida and various other disgusting substances were tried, and the reaction seemed to be proportionate to the revulsion of the patient." Bennett and Venables¹⁸ showed a striking fall in the acid curve and much delayed emptying with the fractional test-meal in an individual to whom they suggested nausea under hypnosis. In disease nausea is especially common in chronic gastritis, whether from alcoholism or oral sepsis, in chronic biliary infections, in jaundice, in severe anæmias, and in the presence of any severe peripheral pain. It is an accompaniment of ocular disturbance, such as astigmatism, and labyrinthine disturbances, such as sea-sickness and Menière's disease. The available evidence suggests that nausea is an inhibition effect—that is to say, it results from conditions opposed to those which induce gastric pain. In this connexion it is interesting to note that (although it is evoked by other severe pain) nausea does not accompany the more painful dyspepsias. It is debatable whether the inhibition accompanying nausea is associated, as some suggest, with the closure of the pylorus which occurs during vomiting. Bile certainly tends to regurgitate into the stomach in association with nausea and retching, and this would rather indicate a relaxation of the pylorus in concert with the general relaxation.

Mention must be made of the confusion which exists between the sensations of nausea and hunger. To feel "sick with hunger" is a popular phrase and has a foundation in truthful observation. The nausea of pregnancy is commonly regarded as a perversion of hunger and may be relieved by food. I have frequently experienced temporary nausea on being abruptly awakened from sleep and called out at night, and on these occasions relief has followed the taking of food. In pathological nausea there is generally not only anorexia but actual loathing for food. Carlson² found in his own starvation experiments that nausea developed towards the end of his five days' fast, but that gastric tonus and peristalsis were increased rather than diminished during this period. He concludes that the changes responsible for this altered sensation may be partly increased irritation of the gastric mucous membrane and partly increased irritability of the central nervous system. It has occurred to me, however, that the nausea which is confused with or accompanies hunger may possibly depend upon the sudden relaxations at the end of strong hunger contractions. In pathological nausea the symptom is frequently described by the patient as "coming in waves," and there seems to be no particular reason why waves of relaxation should not under certain circumstances be appreciable in addition to, or at the expense of, the waves of contraction.

OTHER DYSPEPTIC SYMPTOMS.

Four other dyspeptic symptoms—heart-burn, water-brash, acid regurgitation, and simple regurgitation of food—are, strictly speaking, oesophageal rather than gastric in origin, but as they depend on derangements of the function of the cardia and accompany motor disturbances of the stomach, they may conveniently be considered here.

The relief effected by alkalies in *heart-burn* has long caused it to be regarded as a symptom of acid regurgitation into the oesophagus, and even of hyperacidity. The symptom must, however, be carefully separated from "acidity," for it can occur in persons with normal curves and achlorhydria, and, as Hurst has shown, cannot be reproduced artificially by hydrochloric acid or organic acids introduced into the oesophagus. Hurst⁷ regards it as due to regurgitation of alcohols resulting from the action of yeasts or sarcinae on carbohydrate food. Others, including Payne and Poulton,¹⁹ believe it to be associated with spasm of the cardia or lower end of the oesophagus. The symptom is usually described as a "burning" sensation, and is felt behind the lower end of the sternum. Most of us experience it at one time or another, but occasionally it becomes a chronic and troublesome complaint. In my own practice it has occurred most frequently in the dyspepsia accompanying the early months of pregnancy, in visceroptosis, and in certain types of nervous dyspepsia. Occasionally it is described in duodenal ulcer, but it is not a common association of organic disease. If Poulton's view is correct the relief with sodium bicarbonate may be due to an increase in size of the fundic air-bubble and relaxation of the cardia.

True *acid regurgitation* is due to reflux of acid chyme into the oesophagus or mouth, where it may give rise to a sour taste and roughening of the teeth. It is the only subjective manifestation of hyperchlorhydria, but is present in only a small proportion of cases. No great reliance can be placed upon the patient's description, for it is often confused with heart-burn, and I have been told by a medical man with complete achlorhydria secondary to cancer of the stomach that he was much troubled by "acid regurgitations." Possibly the symptom may have been due to organic acids in his case.

Water-brash, or the regurgitation of mouthfuls of clear, tasteless fluid, is believed by Hurst²⁰ to result from accumulations of ordinary saliva and mucus in the oesophagus, owing partly to excessive secretion and partly to reflex closure of the cardia. I have myself seen it most frequently in cases of duodenal ulcer, and it is common in chronic gastritis.

Regurgitation of food from the stomach without straining, retching, or nausea, should be distinguished from the trick of rumination, and is due to relaxation of the cardia. In the few cases in which I have noted the symptom it has been an association of physical fatigue and mental anxiety in hyposthenic individuals. It was best exemplified by the case of a medical student who only developed it at times when an examination was imminent and he was taking no exercise; physical and radiographic examination revealed no abnormality. It is important to recognise that regurgitation of unaltered food from the oesophagus occurs in the opposite condition of achalasia of the cardia.

DISTURBANCES OF MOTOR FUNCTION.

The subjective manifestations of disturbed tonus have been considered in the foregoing sections, and although by a comparison of these with the habitus of the patient and with other associated symptoms and signs it may be possible to suspect clinically what the radiologist graphically reveals, it is obvious that no precise clinical estimate of tonus can be expected. There are no direct objective physical signs of hypertonus and hypotonus excepting in the extreme examples which accompany respectively the earlier and very late phases of duodenal or pyloric stenosis. These signs are more correctly discussed under the section dealing with disturbances of motility or emptying-rate. The radiographic signs of hypertonus include: (a) high position of the stomach with the pylorus low in relation to the greater curvature; (b) transverse direction of the long axis of the organ; (c) high position of the upper fluid level; (d) normal or less than normal content. These signs

are, as Carman²¹ points out, more likely to be of pathological import if they do not correspond with the habitus of the patient. Occurring in about 17 per cent. of healthy men and 7 per cent. of healthy women hypertonus is found with greater frequency in certain classes of dyspepsia, and particularly in the reflex dyspepsias due to duodenal ulcer and gall-bladder disease. We have no evidence as to the frequency of hypertonus in these conditions before the development of the irritative lesion.

The radiographic signs of hypotonus include (a) low position of the greater curvature, with the pylorus high in relationship to it; (b) vertical position with "J"-shaped stomach; (c) low position of the upper fluid level; (d) content normal or larger than normal. Occurring in 4 per cent. of healthy men and 15 per cent. of healthy women the incidence of hypotonus, usually without any gastric lesion, is much higher in the various conditions causing general debility and in visceroptosis; in association with ulcers of the lesser curvature in women considerable degrees of hypotonus are also found. There is seldom any justification for a diagnosis of "atony" or "dilated stomach" excepting in the presence of signs pointing to pyloric or duodenal obstruction, or to prolonged or repeated "pylorospasm" of reflex origin. Excepting in "acute dilatation" of the stomach, which is now believed to be due to obstruction of the third part of the duodenum by the mesenteric vessels, atonic dilatation is always a process of gradual development.

Finally, tonus may be greatly modified or altogether abolished in infiltrating diseases such as carcinoma and syphilis of the stomach. Care on the part of the radiologist is sometimes necessary to distinguish between a small high-placed hypertonic organ with rapid emptying, and a stomach with diffuse carcinoma of its wall, a narrowed lumen, and rapid evacuation due to rigidity of the pyloric canal.

PERISTALSIS.

The subjective symptom of excessive peristalsis is recurring pain of a griping or colicky character, in which the passage of the pain from left to right may be noted by the patient himself. It occurs in acute indigestion from unsuitable or irritating food, and in a chronic and more severe form is seen only with lesions which obstruct the pylorus or first part of the duodenum. Peristalsis visible through the abdominal wall nearly always implies organic obstruction. From the radiologist's point of view the abnormalities of peristalsis include (a) an increase in the number and depth of the waves; (b) irregularity in the occurrence of the waves; (c) anti-peristalsis; (d) absence of peristalsis. Hyper-peristalsis, with increase in the number and depth of the waves involving both curvatures, is most commonly seen in association with a constricting duodenal ulcer. It may, however, accompany non-obstructive duodenal ulcer or the reflex dyspepsias due to appendicular or gall-bladder disease, conditions in which "pylorospasm" is presumed to occur; Carman²¹ states that under these circumstances there is less tendency to exaggeration of the depth of the waves. He also observes that the hyper-peristalsis of pyloric or præ-pyloric obstruction from growth is more erratic in character and affects chiefly the greater curvature. Anti-peristalsis, in his experience and that of most radiologists, is nearly always due to organic obstructive disease.

All the extreme disorders of tonus and peristalsis are therefore seen to be associated with organic disease of the pylorus or duodenum, or with conditions producing "pylorospasm." The balloon experiments of Carlson² confirm the clinical and radiographic observations with regard to the augmentation of tonus and peristalsis in the early stages of obstruction. The more complete the obliteration of the pyloric lumen and the longer its duration, the more irregular and intermittent become the peristaltic contractions. In the final stage the appearance after a barium meal is that of a greatly dilated, atonic,

and inert sack with the greater curvature low in the pelvis. Peristalsis is also abolished by infiltrating disease of the stomach wall.

MOTILITY (OR EMPTYING-RATE).

Motility may be either impaired or exaggerated by disease. The clinical signs of impaired emptying are vomiting, enlargement of the stomach, and visible peristalsis. Vomiting, it need hardly be stated, occurs as the result of a great variety of local and peripheral stimuli. Thus it may be due to irritation of the gastric mucosa, to general fatigue, to local gastric fatigue through over-eating, to intoxications, to central nervous lesions and psychic disturbances, to spasm or organic narrowing of the pylorus or the duodenum, to mid-gastric constrictions, or to inflammatory or obstructive lesions lower down in the alimentary tract.

The movements bringing about the act of vomiting are largely extra-gastric, and need not here be separately discussed. The pyloric end of the stomach is in strong contraction during the act, while the resistance of the cardia is overcome by the great increase of pressure in the fundic portion produced by the combination of the pyloric closure, descent of the diaphragm, and contraction of the abdominal muscles. I was recently demonstrating a case of pyloric obstruction with visible peristalsis to my clinical clerks when one of them observed a definite reverse peristaltic contraction. Exactly at that moment the patient, who had not been complaining, exclaimed that he felt an urgent desire to be sick. It is possible that the act of vomiting, even apart from obstruction, may be associated with reverse peristalsis.

From the appearance, odour, amount, acidity, and bacterial content of the vomitus in chronic cases and from the length of time over which recognisable particles of food are retained, it has long been customary to decide between organic and functional pyloric closure, and even to draw conclusions as to the cause of the obstruction. Visible peristalsis and enlargement of the stomach to palpation may become apparent before extreme dilatation and stenosis have developed, and even occasionally before delay and stenosis are radiographically demonstrable. In this stage the stomach muscle is hypertrophied and by its hypertrophy and vigour is successful in overcoming the obstruction. With improved methods of diagnosis and earlier and more skilful surgery the extreme degrees of gastric dilatation with persistent succussion splash and copious obstructive vomiting have now become comparatively rare.

From the radiographic point of view delay of a substantial portion of a barium meal beyond the six-hour limit is due to organic obstructive disease. In cases of great loss of tone from general ill-health, when the stomach is low in the pelvis, there may occasionally be delay even up to six hours if the patient is in the erect posture, but by lying down, and particularly by turning on the right side, emptying within normal limits of time may be encouraged. Delayed emptying may also be estimated by the Ewald test-meal, and a simple practical method of determining the presence of pyloric stenosis is that attributed by Cohnheim²² to Boas, in which a meal including raisins or currants is given overnight and the stomach is emptied with an ordinary gastric tube or Senoran's evacuator in the morning. In the presence of obstruction the more fluid portion of the meal escapes but the raisins remain.

Abnormally rapid emptying or hypermotility occurs in a certain proportion of cases of duodenal ulcer with hypertonus; in carcinoma ventriculi, with a rigid pylorus; in association with achylia gastrica, in which a condition of pyloric insufficiency is present; and after gastro-jejunostomy and partial gastrectomy. Rapid emptying can only be inferred indirectly by clinical means. An unduly rapid development of sinking sensations or of pain in duodenal ulcer; morning diarrhoea or post-prandial diarrhoea in so-called achylia gastrica and in Addison's anæmia;

and post-prandial discomforts in the small intestine after a gastro-jejunostomy may all suggest the presence of the abnormality. In any of these conditions the barium meal may be completely evacuated from the stomach within periods as short as two hours or even less.

With the fractional test-meal the rate of emptying and the factors prolonging or shortening it are readily

CHART 10.

Achlorhydria. Addison's anæmia.

studied. The information obtained with the gastric tube is probably more accurate than by other methods and we have the advantage of a normal standard for comparison. In cases of moderately advanced or extreme stenosis or obstruction the test serves the purpose of a 12-hour as well as a fractional test, and the resting juice contains a turbid malodorous residue from the day before. In less advanced cases of duodenal stenosis large quantities of clear and highly acid juice are withdrawn in the first specimen. In the absence of such indisputable evidence in the resting fraction delayed evacuation of the gruel beyond three hours is nearly always found to depend on organic disease, but other evidence than prolongation of the meal should be sought. When, for instance, sedimentation in the rack of tubes has taken place it is noticed that the level of the gruel, instead of falling steadily in the later specimens, is maintained, while in cases due to stenosis from ulcer there is an increase in the clear supernatant fluid. Reflux from the duodenum is naturally inhibited by stenosis, and bile regurgitation was completely absent in 11 out of 12 cases of pyloric stenosis and obstruction whose test-meal findings I have previously reported.²³ Active evolution of gas may sometimes be observed in the specimens. Chemical findings to be discussed later serve to indicate the cause and degree of the stasis, so that with organic narrowing of the pylorus the fractional method becomes a diagnostic test. In all other conditions it supplies evidence only as to the type of the functional derangement.

In the conditions showing hypermotility the fractional test-meal shows disappearance of starch in periods varying from half an hour to one hour. If the hypermotility is due to hypertonus there is a high curve of acidity; if it is due to a patent pylorus there is a low curve or achlorhydria.

DISTURBANCES OF SECRETORY FUNCTION.

The only symptom directly suggesting hyperchlorhydria is acid regurgitation; its unreliability has already been mentioned, and it is obviously secondary to motor disturbances. There is no direct clinical evidence of hypochlorhydria, achlorhydria, or achylia, but the presence of the two last-named symptoms may occasionally be surmised from associated symptoms such as acne rosacea and painless diarrhoea. This lack of any direct subjective evidence of secretory abnormality is wholly consistent with the opinion already emphasised that gastric sensibility is a function of the musculature and not in any way to be related to chemical changes.

Although extreme degrees of hyperchlorhydria and complete achylia (as has been shown) may be associated with perfect health and comfortable digestion, this does not imply that the symptoms have no clinical significance, for it is beyond dispute that both occur with a much greater frequency in disease. In a series of 187 cases of dyspepsia from all causes personally collected and investigated I found 62 per cent. of normal curves, while 30 per cent. showed hyperchlorhydria and 8 per cent. achlorhydria. The incidence of the two extreme conditions was thus nearly four times the normal in the case of hyperchlorhydria, and double the normal in the case of achlorhydria. In Bell's²⁴ much larger series (vide Table V.), which includes other than dyspeptic diseases, the figures were as follows: Normal curves, 61 per cent.; hyperchlorhydria, 24 per cent.; achlorhydria, 15 per cent.; hyperchlorhydria here showing three times and achlorhydria rather more than three times the normal incidence.

TABLE V. (Bell.)

A Comparison Between the Percentage Incidence of the Six Types of Curves in Various Diseases, with the Normal.

Disease.	Number of cases.	Percentages.					
		Achlorhydria.	Hypochlorhydria.	Low normal.	Normal.	High normal.	Hyperchlorhydria.
Normal (Bennett and Ryle) . . .	100	4.0	1.0	10.0	59.0	18.0	8.0
Chronic gastritis . . .	11	45.4	18.1	9.0	0	18.1	9.0
Gastric ulcer . . .	24	4.1	12.5	16.6	20.8	25.0	20.8
Carc. of stomach . . .	10	30.0	30.0	20.0	10.0	10.0	0

Psychasthenia . . .	11	9.0	18.1	9.0	45.4	18.1	0

The mechanism of hyperchlorhydria in health has already been discussed. There is no essential difference in its mechanism in disease, excepting that the causal factors—namely, hypertonus and hypermotility—are exaggerated, and that there is reason to suppose that in certain conditions a positive hypersecretion may occur. In hypersecretion, which is an accompaniment of duodenal or pre-pyloric ulcer, there is a very copious, clear, and highly acid resting juice with continued secretion after the conclusion of the test-meal. According to Bolton,²⁵ however, the only indisputable evidence of hypersecretion is a "rapid rise in the total chloride curve, with or without a similar rise in the HCl curve in the early stage of digestion when the stomach is full, provided the organ is not emptying rapidly."

Hypochlorhydria and achlorhydria in disease are due to (1) excessive neutralisation consequent upon abnormal patency of the pylorus or the presence of a gastro-jejunostomy; (2) neutralisation by the alkaline and albuminous exudates from the surface of a malignant growth; and (3) neutralisation and inhibition of acid secretion by an excessive output of mucus, as in gastritis.

Complete achylia or absence of secretion has by some been presumed to depend upon atrophy of the

CHART 11.

Achlorhydria. Leather-bottle stomach.

gastric glands. Faber regards it as a result of pathological changes consequent upon past gastritis. Hurst,²⁷ as also did Martius,²⁸ regards it as an inborn error of function, and considers that gastritis is more often secondary to achylia than achylia to gastritis. The discovery of achylia in a small percentage of healthy men and in the healthy members of families with a history of Addison's anaemia supports Hurst's view. I have formed the impression from a few case-histories that scarlet fever which, as Brinton¹ showed, is capable of producing a very severe desquamative gastritis, may be a cause of subsequent achylia. One of the four healthy men with achylia in Bennett and Ryle's series was found on subsequent inquiry to have had scarlet fever in childhood followed by a slight persistent albuminuria.

There are no constant distinguishing features in the ordinary test-meal curves between a secondary achlorhydria and a primary achylia. In primary achylia there is a very narrow interval and close parallelism between the curve of total acidity and the base line (vide Chart 10), and the condition persists after lavage. A wide interval between the curve of total acidity and the base line and a lack of parallelism is more likely to occur in a secondary achlorhydria, and is best seen in cases of obstructive carcinoma. The presence of blood strongly favours a diagnosis of carcinoma. In gastritis the presence of mucus in large quantities is an accompaniment of the achlorhydria and the fasting specimen may have a peculiar rancid odour; normal curves may be obtained after lavage and treatment. A comparison of Charts 10, 11 and 12, from cases of Addison's anaemia, leather-

bottle stomach, and gastritis with acne rosacea will show that no diagnosis can be based on a simple study of the chart of acidity alone. Lacking other evidence, a repetition of the test-meal after lavage and chloride estimations may be necessary to distinguish between an achylia and a secondary achlorhydria.

Achlorhydria and achylia are encountered with greater frequency than in health in a variety of general diseases. In Addison's anaemia, with which subacute combined degeneration of the cord is included by Hurst and Bell,²⁹ it is a constant finding. Reference to Bell's series gives an idea of the increased incidence of achlorhydria in certain general and local conditions, including multiple infective arthritis, appendicitis, and gall-stones. Others have reported its frequent occurrence in pellagra and sprue and gout. In some of these conditions, but particularly in Addison's anaemia and in gastrogenous diarrhoea, recognition of the achylia or achlorhydria is of more than academic interest, for it calls for the therapeutic administration of hydrochloric acid.

Hunter,³⁰ employing the fractional test-meal and examining 174 cases of gastro-intestinal disease (in which the diagnosis was confirmed at operation or by biopsy, autopsy, or indisputable clinical evidence), found that in chronic duodenal ulcer 88 per cent. of the cases showed curves above the limits of normal; in ulcer at the pyloric end of the stomach, 67 per cent. of the curves were above the limits of normal; in chronic ulcer of the body of the stomach 50 per cent. of the curves were within normal limits, while 35 per cent. rose above these limits. In cases of

CHART 12.

Achlorhydria. Gastritis with acne rosacea.

hour-glass stomach there was hypochlorhydria; in hour-glass stomach complicated by pyloric stenosis there was usually hyperchlorhydria. In cases of carcinoma of the stomach 67 per cent. showed complete achlorhydria, while 32 per cent. of the curves were within or above the limits of normal. In viscerotoposis there was achlorhydria in 70 per cent. of cases.

Reviewing the conclusions of the foregoing sections we find that most pronounced variations in acidity can be related to disturbances in the function of the

pylorus with which the pars pylorica should probably be included. The exceptions to this generalisation are (1) primary achylia; (2) secondary achlorhydria from disease involving the mucous membrane itself; and (3) the reflex hypersecretion which accompanies some cases of duodenal and præpyloric ulcer.

There is no longer any justification for the employment of "hyperchlorhydria" and "achlorhydria" in a diagnostic sense. The majority of dyspeptic cases which would formerly have been diagnosed as "hyperchlorhydria" are now shown to have either a duodenal ulcer or some other organic irritative lesion. The majority of cases showing achlorhydria are found to be suffering from pyloric insufficiency with gastric hypotonus due to general causes; from local diseases such as gastritis or carcinoma involving the gastric mucous membrane; or from general diseases such as Addison's anæmia.

SUMMARY.

1. The nature and probable causes of the common gastric symptoms have been discussed and evidence for their dependence upon an exaggeration or inhibition of normal tonus, peristalsis, or motility has been given. Whereas pain and discomfort are probably associated with an increase of tension in the muscle-fibre, it is suggested that anorexia (other than that due to rigidity of the stomach wall) and nausea are associated with abnormal relaxations of the muscle-fibre.

2. The common derangements of motor function and the methods of studying them have been briefly reviewed. Motility (or emptying-rate) and the factors disturbing it are more completely and accurately studied with the gastric tube than by other methods.

3. Although actual hypersecretion and hyposecretion of the gastric hydrochloric acid may occur under certain conditions, reasons are given for supposing that pathological hyperchlorhydria, hypochlorhydria, and achlorhydria generally depend upon motor disturbances influencing in one direction or another the rate at which neutralisation occurs.

THE DIAGNOSIS OF MALIGNANT DISEASE OF THE THYROID.

By A. J. WALTON, M.S. LOND., F.R.C.S. ENG.,
SURGEON, LONDON HOSPITAL.

THE whole subject of carcinoma of the thyroid presents so many curious anomalies that no certain statements can be made which are true for all varieties. It is often stated that the disease is so malignant that once the diagnosis can be definitely made the prognosis is hopeless; but in more recent work there has been a tendency, in the statistics at least, to show that the outlook is quite good. These diverse statements are clearly due to the inclusion of several very different conditions, and, therefore, before it is in any way possible to discuss the diagnosis it will be necessary briefly to consider the frequency of the disease and the various pathological and clinical types.

Malignant goitre is usually found in patients of middle age, most frequently between the ages of 40 and 50. The youngest patients in my series were two males, aged 21 and 37, and one female, aged 34. The oldest was a female aged 79. Most investigators find that the condition is twice as common in females as in males, this being the ratio in Wilson's series.¹³ In my own group of 13 cases there were nine females and four males.

In the majority of my cases the diagnosis has been proved by microscopic examination; two have not been operated upon owing to the advanced condition, but both of these have pursued the characteristic course of advanced carcinoma, and the diagnosis, therefore, can be accepted. In the same period of time there have been 402 cases of innocent tumour of the thyroid which have been subjected to operation. Thus in this operative series the frequency has been about 3.2 per cent. There are, however, not included in these figures a large number of cases of colloid goitre and small localised adenomata which have been seen in the hospital out-patient department, and of which—unless a special series is observed for the results of treatment—I keep no private notes; hence the frequency in the total number of cases is probably somewhere about half of this figure—i.e., 1.6 per cent. It is in this question of frequency that such varying figures are found in the literature. Balfour¹ found 103 cases of carcinoma in 6359 of goitre, a percentage of 1.6, whereas Speese and Brown¹¹ found the frequency as high as 4.6 per cent. They believe that this difference may be accounted for owing to the fact that their cases came from a non-goitrous region, whereas Balfour's were obtained from an endemic goitrous area. Wilson,¹³ in his investigations, found that the incidence of malignant disease was as high as 1 in 15.

Difficulties of Diagnosis and Classification.

In my own experience the morphological characters, whether micro- or macroscopic, have been of little or no help in determining the clinical course of the disease or in estimating the measure of its malignancy. Pemberton's⁸ classification into sarcoma, carcinoma, malignant adenoma, and malignant papilloma, although of pathological interest, is of little use, for these different varieties do not give rise to constant clinical types. Of two of my cases showing very similar enlargements of the thyroid, and both described as "mixed-celled carcinoma," one died of extensive recurrence after five months, whilst the other, although developing a local recurrence which was treated with X rays, is alive and well over three years after the operation. De Quervain⁵ has also laid stress upon these difficulties, and he states that the term "malignant goitre" must still be used because it is impossible to differentiate the varying histological types clinically; indeed, it is not possible to distinguish cancer from sarcoma. With the latter part of his statement all will agree, and indeed this subject presents enormous difficulties even to the pure

pathologist, for, as Wilson has pointed out, the sarcomata are peculiar in that besides the connective-tissue elements, of which any form of sarcoma may predominate, there are almost invariably present large or small groups of parenchymatous cells which are also proliferating. He states that it is therefore difficult to say whether the original tumour was formed of proliferating carcinoma cells with a later growth of the connective-tissue elements, or whether the connective-tissue change was primary and there was a secondary stimulation of the parenchymatous cells. At the London Hospital all these mixed cases are reported as "carcinoma sarcomatoides," of which there were four in my own series. To my mind, the almost constant appearance of the carcinoma cells in the cases of sarcoma is a strong argument in favour of the view that these tumours arise from groups of embryonic cells, for in their growth such cells might be expected to differentiate along the connective tissue or epithelial cell path, or even along both.

The difficulties are increased by the fact that many lesions of the thyroid which ultimately pursue a clinical course that is clearly innocent show a microscopic picture which would be passed as malignant. The close simulation that microscopic sections of some cases of exophthalmic goitre show to carcinoma is well known, and in one of my cases (No. 1A) such a diagnosis was made because the cells had spread widely into the lymphatics. The appearance of the thyroid clinically and at operation also suggested this diagnosis, but the subsequent progress has given no evidence of the presence of any carcinomatous change, and I doubt very much, therefore, whether I ought to have included this case in the list of carcinomata. The difficulties that have arisen in the cases of the proliferating goitre of Langhans or the toxic adenoma of Plummer, and to which attention will later have to be given, are also well known. For these reasons, then, any pathological classification must in the present state of our knowledge be regarded as unsatisfactory, and resource will have to be made to a clinical grouping.

Clinical Varieties.

In my own cases three quite distinct clinical varieties can be recognised: (1) Those occurring secondary to adenoma or a colloid enlargement; (2) those which are apparently carcinomatous from the onset; (3) those showing a slowly-growing primary lesion with large secondary deposits. In such cases the primary lesion is frequently overlooked.

Cases Occurring Secondary to an Adenoma or Colloid Enlargement.

In my own series there were five such cases, four being females and one a male. The presence of such a group has long been recognised, but very different figures have been given as to the frequency of any previous lesion. Speese and Brown, in their careful investigation of 25 cases of carcinoma and three of sarcoma, found that there had been a previous adenoma or colloid goitre in 78.5 per cent. of the cases, and the average time at which a simple lesion had been present before the onset of malignancy was 12 $\frac{1}{10}$ years. Wilson,¹³ Plummer,⁹ and Balfour¹ believe that the association of malignant disease with a previous benign lesion is almost invariable, and Berry² has shown that a careful examination will often reveal the presence of some evidence of previous disease. Chambers⁴ states, however, that taking into consideration the slow growth of some cases of carcinoma it is possible that in many instances the condition is rather one of continuous slow development of a malignant goitre than of malignant disease superimposed on a benign growth.

My own cases in this group all show, as will be seen by the table, a prolonged period ranging from 2 $\frac{1}{2}$ –35 years in which a tumour having only benign characters had been recognised, and it is not possible to believe that over such long periods the tumour was already malignant. It is in this group that the first evidence of malignancy is often shown by the presence of some hyperthyroidism, due to a cellular

proliferation within the capsule of the gland, and I believe that too much stress cannot be laid upon the work of Plummer and Wilson in this respect. The latter¹⁴ found that of 97 cases who had died of the disease or who had had recurrence after operation in the Mayo Clinic, there were 50 whose clinical history before the first operation contained no suggestion of malignancy, and 23 of these thyroids were even passed by a pathologist without suspicion of malignancy. He believes that the first evidence of proliferation is hypermetabolism with cardiac disturbances—the toxic adenoma of Plummer. If the proliferation continues it penetrates the capsule, invades and metastasises, and is then frankly malignant. Histologically, it may be impossible to distinguish the foetal adenoma from carcinoma. Hence he states that any sizable adenoma composed of embryonal tissue, if in a patient of cancer age, is potentially malignant. With this my own experience agrees, and I would therefore regard the onset of hyperthyroidism in any adenoma as a strong piece of evidence of the onset of carcinoma, and would advocate early operation in any such case. Later, when the cells break through the capsule, more definite evidence of carcinoma arises, but it is interesting to note that for a time such cases are relatively slow in their progress, and hence the prognosis may be still quite good.

Usually the first evidence of such change is a more rapid growth of the localised nodule, but the mere presence of such a change must not in itself be taken as definite evidence of carcinoma. There are a considerable number of other conditions which will give rise to such a rapid increase. Perhaps the most frequent of these is the presence of an intracystic hæmorrhage, and the fact that this may cause a rapid enlargement and a sudden increase in the dyspnoea is well known. The enlargement due to a hæmorrhage is often, however, much more sudden than that due to the onset of carcinoma, although the rate of increase will naturally depend upon the amount of bleeding. More suggestive of carcinoma is the rapid increase in size which occurs with an inflammatory change. This will give rise to considerable difficulty in the diagnosis, for not only is the mass increased in size but its outline becomes more ill-defined, and it may become firmly adherent to the trachea and sometimes even to the surrounding structures. Its outline, however, is as a rule less nodular than in the case of a carcinoma. Another difficulty may arise owing to the fact that some of the tumours which have undergone a definite carcinomatous degeneration may not always show a rapid onset in the growth. Wilson¹³ found that such an increased rate of growth was only present in one-third of the cases, whereas another one-third had noticed symptoms of continuous growth for ten years or more, and even of those that were inoperable at the time of their examination one-quarter had noticed symptoms which might have been interpreted as indications of the presence of malignancy for ten years or more.

An important change which is usually seen at the same time as the increase in size is an irregularity of the outline and a firmer consistency of the mass. Similar changes may be seen in an adenoma which has been cystic and calcareous, but unless there be coincident inflammation there will not be the same measure of fixation. A rapid increase in size due to inflammation or hæmorrhage may be equally hard but will rarely be so nodular. It must also be remembered that an adenoma in a patient who has become pregnant not infrequently becomes larger and considerably harder, and hence may be mistaken for a carcinomatous change. As a general rule no operation should be performed for goitre on a pregnant patient if it can possibly be avoided. In all the above conditions there is rarely the same irregularity, the presence of which is distinctly suggestive of the onset of carcinoma. Care must, however, be taken not to mistake one large adenoma with several small outlying adenomatous patches for the irregularity of one neoplastic mass.

TABLE I.

Name.	Date.	Sex and age.	Swelling.	Progressive symptoms.	(a) Hypr. thy. (b) Condition of thyroid.	Pressure symptoms.	(a) Fixation. (b) Dilated vessels.	(a) Lymph glands. (b) Secondaries.	Condition at first operation.	First operation.	Pathological report.	(a) After progress. (b) After treatment.

An early and suggestive symptom is the presence of pain. Radiating and neuralgic pain passing from the lobe of the thyroid up the corresponding side of the neck to the back of the head is in most cases due to the presence of carcinoma. It may, however, occur when a fairly acute inflammatory change has taken place in the thyroid. If it be due to a sudden increase of tension, such as occurs with hæmorrhage, the pain is much more likely to be localised to the site of the swelling. With the onset of pain the mass will become fixed. It is important to remember that a simple adenoma is freely movable both upon the trachea and the surrounding tissues. If it has become carcinomatous it usually first becomes fixed to the trachea, and may be definitely malignant although it is still freely movable on the surrounding tissues. Stress is not sufficiently often laid upon this fact, and fixation to the trachea is often regarded as a character of all thyroid tumours. Care must therefore be taken in

LATER PROGRESS.

(Continued from opposite page.)

TABLE I.

- A1.—Myxœdema ceased. Swelling rapidly disappeared. At end of year thyroid not felt. Still myxœdema controlled by extract. Diffuse alopecia after 2 years; improved. Still myxœdema after 7 years; controlled. Married, with 1 child.
 A2.—After 7 years quite well.
 A3.—Gradual improvement. Three years later quite well. Still small swelling upper border of thyroid.
 A5.—Died of recurrence 4 months after operation.

TABLE II.

- B1.—Well 8 months, then failed to report.
 B2.—Perfectly well after 18 months. No recurrence since.
 B5.—Operation low tracheotomy, 18/8/19. Died 5 weeks after second operation.
 B6.—Died 6 months later of recurrences in lung.

TABLE III.

- C1.—Some improvement in axillary swelling.

the examination to fix the trachea and to estimate the mobility of the mass upon it. With the continued spread of the growth beyond its capsule the next structures to be involved are, as a rule, the pretracheal muscles; as these become infiltrated there will clinically be a further amount of fixation and the nodular appearance on the surface will become much more evident. A distinct increase of pressure upon surrounding structures giving rise to dyspnoea, dysphagia, hoarseness and coughing, or clear evidence of interference with the recurrent laryngeal nerves, are all suggestive, but, as with the other symptoms, any one of these alone must not be taken as clearly indicative of carcinoma. It used frequently to be stated that a paralysis of one side of the larynx was diagnostic of carcinoma. It is now known, however, that a simple adenoma may project posteriorly and interfere sufficiently with the recurrent laryngeal nerve to cause a similar weakness of that side of the larynx. It is rather on the presence of several of these physical signs than of one alone that a diagnosis of carcinoma will be made. In the later stage infiltration of the skin, with redness, marked dilatation of the veins, and the presence of blood-stained sputum will make the diagnosis evident. Enlargement of the lymphatic glands is also suggestive but is not certain evidence of carcinoma, for an inflammatory lesion may also cause glandular enlargement. The nature of the enlargement is of more importance. In the former case the glands are harder and more sharply defined unless the carcinoma has broken through them and involved the surrounding tissues. These changes are usually quite distinct from the softer and more tender enlargement which is inflammatory in nature. The presence of such glandular enlargement may be found relatively early, and is thus not in itself a necessary counter-indication to operation.

The difficulties of making a diagnosis in the early stages are perhaps less in this than in the other groups, but are very considerable. The presence of a certain amount of hyperthyroidism I would regard as of great import, for even if it is not due to the

actual onset of carcinoma it will give rise in time to severe toxic changes, and thus is an indication for operation even in elderly and feeble patients. It was present in three of the five of my cases in this group. Of the other symptoms rapid growth, increased hardness, irregularity, and tracheal fixation may all occur early, and although each one alone may occur with other conditions the presence of two or more are very suggestive. If operation be performed in these earlier stages the prognosis is not so absolutely hopeless as it is often thought. Of my five cases the first, which perhaps should not be included, has developed myxœdema but is alive and otherwise well ten years after operation; the second is quite well seven years after operation; one had a recurrence which has been kept under control and has indeed decreased in size with X rays, the patient being alive and feeling in perfect health three years after operation; the fourth is free of any evidence of recurrence two years after operation, and the fifth died with evidence of recurrence a few months after operation. (Table I.)

Cases which are Apparently Carcinomatous from the Onset.

This group in my series was slightly more common than the last, there being seven such cases, five females and one a male. In nearly every case the first symptom noticed was a swelling in the neck which rapidly grew and within a short time of the onset was associated with pain or the onset of pressure symptoms. Porter¹⁰ states that as a rule this variety occurs in people beyond middle life, usually as a unilateral and less frequently as a bilateral goitre, and grows steadily or rapidly. It will be seen, however, that in my series one of the patients was only 21 at the time of onset, although the majority were over the age of 40. The longest history that was obtained was of one year, and in this case (No. B2) the growth was relatively benign in that even at the end of this period the tumour on clinical examination still appeared to be limited to the thyroid gland. It was, however, of special interest in that at operation it was not only adherent to the trachea but the whole of the right lobe was found to be involved and the growth had spread to the pretracheal muscles, so that these structures were infiltrated with a material resembling sago pudding in its consistency. Nevertheless, a wide removal of the right lobe and the overlying pre-tracheal muscles was followed by a rapid cure, and the patient has since remained free of all evidence of recurrence, a period of nine years. In three of the cases the tumour was limited to one lobe and showed the general appearance of an adenoma, but in all of these the mass was considerably harder than would have been expected if the lesion had only been an adenoma. In one it was nodular in outline and in the third it was adherent to the trachea—that is to say, in two of the three cases there was fairly definite evidence of carcinoma on clinical examination, so that the physical signs taken with the short history and rapid growth made the diagnosis probable. In the remaining cases the growth was more diffuse, a whole lobe or more of the gland being involved. It is in this group that a considerable amount of difficulty will be found in making a correct diagnosis, and this will chiefly lie in the direction of mistaking non-malignant conditions for carcinoma.

This variety of growth usually presents a short history, there is a diffuse enlargement of one lobe or more of the gland, the enlargement is hard, is often irregular and is fixed to the trachea. There is often a considerable amount of pain, probably owing to the rapid growth. The mass is not only fixed to the trachea but there may be a distinct amount of dyspnoea and often some difficulty in swallowing. Although these changes are very suggestive of carcinoma, I have had three such cases where a positive diagnosis of growth was made, but an operation was not advised either because of the patient's age or because the size and fixation to the trachea gave rise

to the belief that the condition was too advanced for an operation to hold out a reasonable hope of cure. The after-progress of these cases has, however, been so slow or the condition has so definitely regressed that it is certain that there is no carcinomatous element. Unfortunately, in such cases the correct diagnosis remains a matter of conjecture, for no portion has been removed for section and it is only possible to believe that the enlargement was due to some inflammatory change.

It is always advised that in these cases a Wassermann test should be carried out, and there is no doubt that in all such doubtful cases it should be performed. I have, however, only once seen a definite case of syphilis of the thyroid. Here there was a localised swelling in every way resembling a simple adenoma, but owing to the strong syphilitic history a Wassermann test was performed and found to be positive, the lesion yielding to appropriate treatment. In not one of the doubtful cases was the test positive. In these inflammatory conditions the swelling is, as a rule, less sharply defined and not quite so hard and irregular.

In this group, as in the last, there is the onset of pain at an early date. At first limited to the site of the lesion, it soon begins to radiate more widely, and frequently passes up to the side of the neck, to the ear, and the side of the head, the patient frequently complaining of earache. Another point which I believe is frequently of value in making a positive diagnosis is that the carotid vessels may be pushed outwards, whereas it is more common in the innocent varieties for these structures to lie deep to the thyroid, which tends to expand forward as it grows. In the later stages the diagnosis becomes the more certain as the prognosis is more hopeless. Dyspnoea increases and there may be the expectoration of blood-stained mucus. Dysphagia is present and there is serious interference with the recurrent laryngeal nerve. The mass, and with it the trachea, becomes more firmly fixed as the growth invades the surrounding tissues. The lymphatic glands above and not infrequently in the posterior triangle become enlarged and hard, and later they in turn become fixed. The superficial veins are dilated and tortuous and the skin may become adherent and reddened.

The important difficulties in diagnosis, therefore, lie in the early stages when there is still some hope of bringing about a cure from surgical interference. In the localised group it may be said, as in the first variety, there is no one sign which is certain evidence of carcinoma. The short history, the steady growth, the hardness, and especially a nodular hardness which distinguishes this condition from a calcified adenoma, and a certain amount of fixation to the trachea will make a positive diagnosis almost certain. In my own experience any definite degree of hyperthyroidism has been absent in this group.

In the diffuse variety the difficulties are much greater, but fortunately the tendency is rather to mistake innocent lesions for carcinoma rather than carcinoma for inflammatory changes, but here again the combination of the short history, the steady progress, the hard mass, and the nodular surface are the important factors. In neither case do I believe that the local removal of a small portion of the growth will be of any value in arriving at a diagnosis. So often both neoplastic and inflammatory changes are combined that the absence of carcinomatous changes in so small a portion would still leave the diagnosis in doubt. It must be remembered here that the younger and more healthy the patient the more readily will operation be advised in all doubtful cases. It is in old, feeble patients on whom any operation of this sort might be a grave danger that such care has to be exercised in excluding inflammatory lesions from the diagnosis.

In this group, as in the other, the prognosis will depend upon the time at which operation is undertaken, but even here there is a great variation in the rate of growth. In one of my cases showing a small mass of only six weeks' duration recurrence took

place four months after operation and death occurred four months after the recurrence, while another with a year's history was well nine years after operation. Of the seven cases three were inoperable when first seen, two died of recurrences within a few months, one was lost sight of after eight months when she was still apparently well, and one remained free of all trouble to date, nine years after operation. (Table II.)

Cases Showing a Slowly-Growing Primary Lesion with Large Secondary Deposits.

There is a curious variety of carcinoma of the thyroid in which the primary lesion is so slowly-growing or is so small that it is frequently overlooked entirely, and this even upon careful examination. Scattered throughout the literature are accounts of cases in which metastatic deposits have occurred, and these most frequently in the long bones. The patient has been subjected to an operation, very often an amputation, in the belief that the condition was one of primary sarcoma of bone, and after operation a microscopic examination revealed the fact that the tissue was apparently carcinoma of the thyroid gland. The most remarkable, perhaps, of these cases is that reported by Sir Frederic Eve,⁷ which occurred at the London Hospital. This was the case of a woman who had a large pulsatile tumour in the upper end of the femur for which an amputation was performed at the hip-joint. At the time of the operation no lesion could be found in the thyroid gland, but some few months after the amputation the gland became enlarged. This enlargement had steadily but very slowly progressed so that at the time of the report, three years after the operation, the thyroid was considerably enlarged, but the patient was in perfect health. There are several points of interest in this group of cases. First, there is the fact that the secondary deposits are more common in the parietes, whereas usually the other varieties when advanced give rise to secondary deposits in the viscera and especially in the lungs. The other point of importance is that the primary growth is relatively benign and slowly growing. De Quervain has laid stress upon this and states that the mildest form of carcinoma of the thyroid is presented by those cases which look innocent but are associated with secondary deposits. In many of these cases the rate of progress is so slow and the metastases so limited in number—it is, in fact, very common to find only one such deposit in a bone—that it is not uncommonly possible to remove a secondary deposit and then to operate upon the condition in the thyroid with a very good chance of obtaining a radical cure. Unfortunately, in a certain number of these cases, even when a metastatic deposit has been removed and the diagnosis of its origin has been made certain by a microscopic examination, it is still impossible to operate upon the thyroid, for the primary lesion is so small that it cannot be discovered.

There occurred in my series only one example of this type of case. This was a male, aged 36, who four years before he was seen had developed a swelling in front of the left ear which had been removed elsewhere. For 18 months the swelling in front of the ear had recurred and a second swelling had developed below the right clavicle. The latter in its clinical characteristics suggested a sarcoma in the pectoralis major muscle. Both swellings were excised, the lower with a surrounding area of healthy muscle, the diagnosis of both masses being doubtful. On microscopic investigation it was found that they were formed of a secondary carcinoma sarcomatoides of the thyroid tissue type, but a most careful examination failed to reveal the presence of any lesion in the thyroid gland. There was no local swelling and no general enlargement. A year after operation he developed enlargements in the axillary glands for which X ray treatment was advocated. Shortly after this he developed dyspeptic symptoms which suggested that there might be secondary deposits in the liver, but no enlargement of that viscus has yet been

determined. With the use of X rays the condition is for the time being held in check and there is still no palpable enlargement of the thyroid gland.

These cases present extreme difficulties in diagnosis, but they are difficulties which are of very little practical importance, for even if the nature of the metastatic deposit is not recognised an operation is usually undertaken, and with so slowly growing a primary lesion and a single metastasis this should be regarded as correct treatment even if the condition were recognised. In every case where any change is manifest in the thyroid gland the affected lobe should also be excised. (Table III.)

THE RENAL THRESHOLD FOR GLUCOSE

IN DIABETES ASSOCIATED WITH NEPHRITIS.*

BY E. WORDLEY, M.C., M.D. CAMB.,
M.R.C.P. LOND.

(From the Pathological Department, South Devon and East Cornwall Hospital, Plymouth.)

It is frequently stated that in chronic nephritis the renal threshold for glucose is raised to a greater or lesser degree. Reference may be made to Bang (1913), Myers and Bailey (1916), and Todd (1923). The latter states that while the renal threshold in such cases is generally raised, it is not always so. During the investigation of a large number of diabetics with a view to establishing their correct insulin dosage, a certain number were found to be suffering from nephritis and diabetes, and observations were accordingly made to see what effect the renal lesion had on the excretion of sugar.

It will be seen that all the cases described below were of middle age or older, and that in all instances the renal lesion was of the chronic and azotæmic type. It will be seen from a study of the figures in individual cases that no evidence was present of increased nitrogen bodies in the blood as shown by the fact that all had a low blood-urea content, but it must be remembered that all these patients were on a reduced diet and a low nitrogen intake. All of them showed, however, a marked inability to concentrate urea, and furnish excellent examples of the fact that MacLean's urea-concentration test (MacLean, 1919) is an exceedingly delicate means of detecting faulty renal excretion.

It is to be noted that few of these cases showed any symptoms suggesting nephritis. The evidence for nephritis is in nearly every case given by a low urea-concentration figure in conjunction with the

presence of protein and casts in the urine, and often a raised blood pressure, except in Case 5, where acute nephritis was present, and the urea-concentration figure normal.

Clinical Records.

The patient in the case here described was a male, aged 52, who had been invalided from the army in 1917 with nephritis, had been in receipt of a pension, and had been regularly attending medical boards since. He complained of shortness of breath, polyuria, and frequent swelling of feet. Pulse irregular; heart enlarged ext: to N.L.; blood pressure 210 mm. Hg. Is a very thin man, looks much older than his years, nose and extremities cyanosed. Sugar was noticed in urine during a recent pension board, and he was sent into hospital for further investigation.

Condition on Admission.—At this time he was passing about 2.5 per cent. sugar on a full diet and was accordingly starved for four days. The sugar was diminished but was still present (1 per cent.) and he was put on a slowly increasing diet, as it appeared impossible to make the urine sugar-free by starvation. He was sent to the laboratory for further investigation, with results as follows.

It was found that on a 900 calorie diet, the blood-sugar was fairly constant at about 0.075 per cent., with a urinary sugar of about 1 per cent. The urine contained much "acetone." The sugar tolerance was investigated with the following results:—

	Resting blood-sugar	Per cent.
	1 hour after 50 g. of glucose by mouth	0.081
1	"	0.162
1½	"	0.218
2	"	0.237
2½	"	0.150
3	"	0.100
3½	"	0.075

Urinary sugar 2½ hours after taking glucose was 7.7 per cent. Urinary sugar secreted between 3 and 3½ hours after taking glucose, when blood-sugar was between 0.100 per cent. and 0.075 per cent., was 5.15 per cent. He was therefore put on a full diet, acetone bodies quickly disappeared from the urine, and the patient felt much better. The ammonia coefficient on a full diet was normal, it became slowly higher as the food intake was reduced. It was found that when he was on a full diet the urinary sugar was fairly constant at about 2.5 per cent., the blood-sugar being about 0.150 per cent.

At this period the renal function was investigated with results as follows:—

Urine, a thick cloud of protein, a few leucocytes present, no casts seen. The urea-concentration test gave a figure of 1.45 per cent. in the second hour. His blood-urea was 33 mg. Thus his urea-concentration was poor, while the blood-urea was normal.

After having been for some period on a full diet, he was submitted to absolute starvation with the exception of water to drink, to find at what level of blood-sugar his urine became sugar-free.

The patient was starved for 106 hours, frequent estimations of blood and urinary sugar being made. The urinary and blood-sugar gradually diminished until at the end of this time the blood-sugar was reduced to the low figure of 0.075 per cent., and even then he was still passing 0.9 per cent. sugar in the urine. By this time the urine reacted very strongly to Rothera's test, and as his condition was rather feeble it was not considered advisable to continue the starvation. It was found that for the first 85 hours of starvation the blood-sugar was constant at about 0.088 per cent., when he was excreting as much as 2.5 per cent. of sugar in the urine; later it slowly fell, as did the urinary sugar to the levels mentioned above.

The effect of a dose of lævulose was next tried, with results as follows. His weight was 10 st.

Thirty-five g. of lævulose were given dissolved in 100 c.cm. of water five hours after last meal, which consisted of two eggs, bread and butter, and tea. Blood-sugar before lævulose, 0.125 per cent.; 30 min. later, 0.168 per cent.; 60 min. later, 0.112 per cent.; 100 min. later, 0.156 per cent.; 130 min. later, 0.202 per cent. Urinary sugar before lævulose, 3.0 per cent.; after lævulose, 3.9 per cent.

It will be seen that after lævulose the blood-sugar rises during the first half-hour, then drops to below the initial figure before the lævulose was given, and then rises again. There was a slight increase in the urinary sugar.

The patient was again put on a full diet, and examination of the blood and urinary sugar gave the same figures as before—i.e., blood-sugar 0.120 per cent. to 0.130 per cent., and urinary sugar about 2.5 per cent. He was then given pil. codein. gr. ½ b.d., to see if this had any effect in

* Being in part the substance of a thesis submitted for the degree of M.D. Cambridge.

decreasing the permeability of the kidney for sugar. Very little, if any, effect was noted, the amount of sugar remaining practically the same.

Commentary.

The interesting point about this case is the very low threshold for sugar in a patient with advanced renal disease. The threshold is, in fact, so low that even if he had no defect in sugar utilisation he would resemble a true diabetic, owing to the inability to store sugar consequent on the continuous loss through the kidneys. Inspection of his blood-sugar curve following ingestion of sugar appears to show that there is some slight defect of sugar utilisation present, also his normal blood-sugar on a full diet is definitely raised in spite of the continuous leak via the kidneys. This defect, however, appears to be slight, and not to need treatment. The patient himself feels much better on a full diet. In addition, the permeability of his kidneys for sugar is the reverse of what is said to be found in patients with advanced renal disease. Further instances of this condition will be quoted later. It should be noted that the blood-urea was not raised, in spite of the fact that the urea-concentration figures showed that the kidneys were seriously damaged, probably due to the low nitrogenous intake. Thus, this case shows an abnormally low renal threshold for sugar and severe nephritis. It also appears that he has a mild degree of diabetes. MacLean (1922) states in his book that this is a rare condition and quotes one case, but in it the renal threshold was only reduced to 0.140. Here the renal threshold for glucose is at the very low figure of about 0.075 or lower.

Details of Additional Cases.

For briefness particulars of the other cases examined are shown in the following table. All were cases with severe diabetes and chronic nephritis. They were all starved until their urine became sugar-free, constant examinations of the blood-sugar being made.

Case.	Age.	Urea-concentration test (per cent.).	Blood pressure (mm. Hg.).	Urine.	Blood-sugar level at which patient was sugar-free (per cent.).	Blood-urea (mg. per 100 c.cm.).
2	54	1.5	200	Alb. + + +. Granular casts numerous.	0.112	44
3	62	0.9	186	Alb., trace. No casts.	0.255	66
4	51	2.0	190	Alb. + + +. Granular casts numerous.	0.184	33
5	67	2.0	186	Alb. +. Hyalo-granular casts (a few).	0.181	32
6	54	1.4	200	Alb. +. Granular casts numerous.	0.181	—
7	58	2.2	178	Alb., cloud. Hyalo-granular casts numerous.	0.172	—
8	58	1.65	190	Alb., cloud. No casts.	0.180	48
9	58	1.6	194	Alb. +. Hyaline casts (a few).	0.186	32
10	41	1.65	190	Alb. + + +. Hyaline casts numerous.	0.186	29

Methods Employed.

The blood-urea was estimated by MacLean's modification of Van Slyke's method (MacLean and De Wesselow (1918)).

Urea was estimated by the hypobromite method. The urea-concentration test was carried out in all cases first thing in the morning before the patient had had breakfast.

Urinary sugar was estimated by Bertrand's method.

Blood-sugar by MacLean's method (MacLean (1919)).

Total nitrogen in urine by Kjeldahl's method.

Ammonia nitrogen in urine by aspiration of air through a measured volume of urine plus sodium bicarbonate, into a measured volume of acid and subsequent titration.

Plasma bicarbonate was estimated by Van Slyke's method Van Slyke (1917)).

Conclusions.

In all, ten cases are described of diabetes associated with renal disease; in all there is present a marked inability to concentrate urea as judged by MacLean's urea-concentration test. In eight of these ten cases the renal threshold for glucose was normal, in spite of the inability of the kidney to concentrate urea. In two cases the renal threshold for glucose was raised, one case (Case 2) slightly, in the other (Case 3) to a greater extent.

It would appear, therefore, that chronic nephritis of the azotæmic type does not, in the majority of cases, alter the permeability of the kidney for glucose. In addition, these observations show that MacLean's urea-concentration test is of greater value in estimating the function of the kidney in diabetes than an estimation of the blood-urea, since the prolonged period during which many of the patients have been on a low diet tends to lower the blood-urea. It is, of course, well known that it is possible, in cases of nephritis, by giving a diet containing very little protein, to reduce the blood-urea, when previously on a full diet it had been very high, to an almost normal figure. Examples have been given in a previous paper (Wordley, 1920).

INCIDENCE OF GLYCOSURIA DURING PREGNANCY.*

BY ARTHUR CROOK, M.R.C.S. ENG.,
 CONSULTING OBSTETRICIAN TO NORWICH MATERNITY
 INSTITUTION.

THESE notes are based on the result of the examination of the urine of 548 patients during their pregnancy. The routine has been generally a monthly examination, supplemented (in those cases in which sugar or albumin was found) by more frequent tests. The total number of urine examinations was 1346, which gives a rough average of between two and three per patient. The specimen of urine examined has not been always the early morning fasting urine, for this would, as pointed out by Joslin, lead to some cases not being detected at all, sugar being present in the urine only after a meal in some patients.

The records date from 1908 to this year, therefore the majority of the cases were under observation before the modern test of the blood-sugar index was in use, and are in many of the cases, due to the exigencies of general practice, very imperfect.

As to the nature of the clinical material, most of the patients belonged to the rather better working classes of a manufacturing town, whose diet is on a more generous scale in the use of meat than in the purely agricultural districts. The cases included some with complications (see Table).

Method of Testing.—Boiling the Fehling solution freshly made in the test-tube and adding the urine, a few drops at a time, and keeping the mixture at boiling point till nearly as much urine as test solution had been used. Later the reaction has been carried out by boiling the test solution and urine separately, and mixing equal volumes, then boiling the mixture for five to ten seconds, and allowing the tube to stand

* Read before the Section of Obstetrics and Gynaecology of the Royal Society of Medicine.

and cool for about a minute. Positive results have been checked by the fermentation method, noting a diminished sp. gr., and again testing the filtered fermented urine for sugar by the same method and finding it absent.

Table showing Incidence of Glycosuria in Cases of Pregnancy with Complications.

Complication.	Total No. of cases.	Glycosuria—		Remarks.
		With.	With-out.	
Eclampsia ..	1	—	1	Severe; 40 fits; recovered.
Acute alcoholism ..	1	—	1	Fatal; nearly full-time gestation.
Morbus cordis ..	7	3	4	—
Syphilis ..	1	—	1	Second stage (untreated).
Chorea ..	1	—	1	—
Tuberculous disease of hip ..	1	—	1	Chronic discharging sinuses.
Mediastinal tumour ..	1	—	1	Secondary growths of suprarenals.
Simple fibrous goitre ..	2	1	1	—
Insanity ..	3	1	2	Morbus cordis in the case with glycosuria.
Uterine fibroids ..	4	3	1	—
Epilepsy ..	1	—	1	—
Pertussis ..	1	1	—	—
Tuberculous meningitis ..	1	1	—	Fatal at third month.
Intractable boils ..	2	2	—	One patient; two pregnancies.

Incidence of Sugar.

Of the 548 patients, 166 had, at some time or other, during pregnancy, sugar in the urine—that is, a little over 30 per cent.; 23 patients had sugar in the urine in more than one pregnancy, but not in all—that is, about 4 per cent.; 8 patients had it in all their recorded pregnancies—that is, nearly 1·5 per cent. Of the 166 detections of sugar, 40 were first noted before the 21st week of pregnancy, while 126 were first detected between the 21st and 40th weeks, the week showing the largest number being the 28th; the next two highest being the 22nd and 30th weeks.

With regard to the 40 cases that were showing sugar at a period of pregnancy not later than the 20th week (if we exclude one quite exceptional case in which the glycosuria was accompanied by pernicious vomiting, albuminuria, and abortion in all three pregnancies), in 24 cases (59 per cent.) it was definitely recorded to have disappeared before the end of the pregnancy; while of the 126 cases in which it was detected first at the 21st week and afterwards, only 34 cases (32 per cent.) are recorded as not showing sugar in the urine again.

Of the 40 early cases, if we exclude the exceptional case before mentioned, there is no record of toxæmia at all, while in the 126 later cases there were 4 with albumin as well, 2 had albumin in the next pregnancy, 1 had sugar still 13 years later, and 1 showed sugar still 10 years afterwards, and 10 had marked signs of toxæmia. One had chorea, and 3 tachycardia of doubtful origin.

It appears from these figures that about 30 per cent. of these pregnant women passed sugar in the urine at some time during their pregnancy, and in about one-third of all the cases and in quite one-half of those which were first detected before the fifth month it was of short duration, and not associated with other serious signs of disturbance of metabolism, while in those cases in which it appeared at about the 28th to 30th week it is more often associated with signs of toxæmia and more allied perhaps to the "renal diabetes" so-called, and in about 10 per cent. of them it lasted till labour and afterwards.

In the small proportion in which the sugar appears in every pregnancy (1·5 per cent.) the proportion of definite toxæmia is higher still, 50 per cent. at least, though the total number of these cases is perhaps too small to allow any conclusion to be reliable. In cases only first detected at a very late date—that is,

after the 34th week—just under 3 per cent. of them had sugar till labour, and afterwards; some of these cases were of the intermittent type.

No special incidence of septic infection was noted in these patients, though it was the rule to record all vaginal discharges, or any septic condition which a complete examination revealed. The average weight at birth of the children of mothers who had glycosuria at any time during pregnancy was 7·2 lb. Sugar was absent in the fasting urine in most of my cases. As to the effect of diet, I found that, if strictly adhered to, it caused the disappearance of the sugar, thus differing from what is generally said to occur in "renal diabetes," and from most of the cases related by Dr. Mackenzie Wallis in his paper read before this Section in November, 1921; but his statement that the sugar is mostly detected about the sixth month, and as to the frequent occurrence of severe vomiting at an earlier period of the pregnancy, corresponds with my experience. In one particular case (No. 2) the result of dieting was disquieting, the urine when sugar-free becoming loaded with acetone, and the patient manifested symptoms of severe weakness and faintness. This appearance of acetone in the urine where there had been none before the dieting was begun, was noticed in the case described by Dr. Graham in his paper before this Section in May, 1924. But that was when the patient was at an early age, and before pregnancy had occurred.

Clinical Records.

CASE 1.—Mrs. —, aged 30; her second pregnancy. No history of first pregnancy. Sugar now present at 33rd week up to 5 gr. per oz.; blood pressure 155 mm. Hg; cedema of legs and troublesome pruritus; normal labour; hydramnios. Third pregnancy: now 37 years old; 31 weeks pregnant; urine containing sugar 5 gr. per oz.; it persisted till 14 days before labour, which was normal, except for hydramnios. This patient had amenorrhœa for four months with enlargement of thyroid and nervous symptoms just before the commencement of this last pregnancy; the thyroid enlargement and nervous signs disappeared with the onset of pregnancy; now, 10 years after, she has no glycosuria or thyroid enlargement, and is in good health and has regular periods.

CASE 2.—Mrs. —, primipara, aged 29; 23 weeks pregnant; sugar in urine (after meals only) 10 gr. per oz., no thirst or polyuria, but excessive frequency of micturition, sometimes half-hourly. Blood-sugar fasting 0·083, after 100 g. glucose, 0·136 after one hour, 0·104 after two hours, 0·079 after three hours. Taken when on ordinary diet at two hours after midday meal, 0·166. Had excessive vomiting and "air hunger" first two months—these symptoms now gone but has pain under right shoulder and in breasts if exposed to cold (it was mid-winter); these symptoms relieved by large doses of sodium bicarbonate. With strict non-carbohydrate diet, urine became sugar-free, but produced symptoms of giddiness and weakness and "drunken feeling" and large quantity of acetone appeared. Sugar reappeared directly carbohydrates were taken even in small quantity, and eventually some present in fasting urine as well; total amount being up to 400 gr. per diem. After premature labour (induced) sugar persisted for six weeks, then disappeared; three months after labour 50 g. glucose gave blood-sugar 0·18 three hours afterwards, and urine showed 9 gr. sugar per oz.

CASE 3.—Mrs. —. Three successive pregnancies: first pregnancy, aged 32; 11 weeks pregnant, seen because of intractable vomiting for 14 days. Pulse 100 (persistent); blood pressure 150–160 mm. Hg; scanty urine, high colour, excessive acid reaction, sugar, and trace albumin; ferric perchloride test positive. Vomiting ceased after one passage of stomach-tube and gastric lavage; urine increased in volume and contained more sugar; a fortnight later aborted spontaneously. Second pregnancy: about eight weeks pregnant; vomiting began a week ago and said to be continuous. Pulse 108, temp. normal. Urine as before but no sugar; volume very scanty. Improved under gastric lavage for a fortnight, and sugar appeared in urine, then relapsed. Blood pressure 120 mm. Hg; pulse up again; delirium at night; total urine 16 oz. per day only. Uterus emptied under anæsthetic and sugar absent from urine by 14th day. Third pregnancy: now aged 33; seen at eighth week, vomiting severely, no sugar but albumin. Seven days later sugar present. Still vomiting continuously; after 12 days, vomiting better, but patient certified for acute mania and removed to mental hospital; discharged in seven weeks recovered. Vomiting still

severe; sugar still present. Pulse persistently over 100; some night delirium; uterus emptied under anæsthetic; large quantity liq. amnii of dark green colour; no sugar in urine three days later. Now, nine years after, has had no more pregnancies, has become very fat, and has no sugar in urine, and periods are regular.

The Question of "Renal Diabetes."

It has been suggested that these cases were really cases of "renal diabetes" such as has been described apart from pregnancy—that is, sugar in the urine, with no hyperglycæmia or other diabetic signs. It appeared in two of my cases to be so—the sugar being still present 10 and 13 years afterwards, and yet the patients still in fair health, certainly not diabetic. In these, too, others of the same family had glycosuria.

In considering this question of renal diabetes and its importance, I mention the work of Barrengen and Roper¹ who, analysing insurance statistics, found that after five years 20 per cent. of their supposed "renal diabetics" had developed diabetes, 25 per cent. were "suspicious," and 55 per cent. remained free. They also noted that if the glycosuria was recurrent—that is, detected more than once—8 out of 11 cases became diabetic. These figures make one hesitate to say the matter is not important.

Types.—Perhaps there are at least two distinct types—first, a benign type, which is generally first noticed before the fifth month, but may only be detected very late in the pregnancy, viz., after the 34th week; this may be transient or intermittent, or may be a condition, unaccompanied by serious symptoms, which was present before the pregnancy, and will persist after it; and secondly, a type where the sugar generally appears at about the 21st to 23rd week, is often accompanied by symptoms usually associated with some toxæmia of pregnancy, and does not disappear till the termination of the pregnancy, and in some cases recurs with succeeding pregnancies. It is especially associated with cases having had severe early vomiting, which often has subsided, and also in the later months with œdema (not necessarily accompanied by albuminuria)—a link perhaps with chloride metabolism, and also sometimes associated with hydramnios.

In connexion with the supposed comparative innocency of glycosuria before the fifth month which I suggest as the result of my experience, it may be of interest to recall that in the early months of pregnancy the detection of sugar in the urine after a glucose meal has been used as a test for pregnancy (Frank and Nothmann). These writers assert that the test is useless after the fourth month, and if that is so, it seems that the normal pregnant woman can meet most demands after that period on her carbohydrate metabolism.

Though the glycosuria met with in pregnancy after the fifth month may have some relation to "renal diabetes" it does not seem to explain all the other cases (excluding of course true diabetics).

The two cases in my series in which sugar is still present in the urine 13 and 10 years after the pregnancy, although still in good health and showing no signs of true diabetes—did not when pregnant present symptoms complained of by the patients who rapidly ceased to pass sugar after labour and the puerperium—such symptoms as, namely, excessive early vomiting, pruritus, considerable œdema of legs without albuminuria, and the presence of hydramnios.

My only excuse for recording these crude figures and the deductions from them I have suggested, must be the present position of our knowledge of pregnancy and so-called "toxic" pregnancy. Recent work on the glands of internal secretion seems, at any rate for a time, to have increased the fog between our eyes and the clear picture we all desire of the relationship (if any) between pregnancy, "toxic" pregnancy, acidosis and carbohydrate metabolism, and otherwise, to each other. My hope is that by placing this fragment, as one may figuratively describe it, on the

table where the parts of an, as yet, unarranged puzzle lie, I may help others to fill the gaps and so aid in its ultimate solution.

PS.—Since finishing these notes, I find that I have overlooked that Dr. Herbert French, quoting Saleim in the Goulstonian Lectures, 1908, gives the incidence of glycosuria in pregnancy as high as 66 per cent., and observes on the frequency of hydramnios in this condition; also a case recorded by Dr. R. Wise and published in the Transactions of this Section in March, 1923, in which death of the foetus occurred at the eighth month of the first pregnancy, while in the second pregnancy the symptoms specially noted in addition to polyuria and thirst were pruritus and faintness, the sugar disappearing after a normal labour with living child. With reference to this tendency to death of the nearly mature foetus before birth, I give very briefly notes of a case occurring to me within the last few weeks. A primipara, aged 35, sugar 2 gr. per oz. found at the 24th week. Hydramnios detected at the 28th week with great œdema of legs. Sudden death of child at 35th week, almost complete subsidence of the œdema and sugar before the birth of a 7½ lb. macerated foetus at the 38th week.

Clinical and Laboratory Notes.

VERONAL POISONING.

WITH NOTES ON A CASE.

By E. P. SCOTT, M.B., B.S. LOND., M.R.C.S. ENG.

IN patients with any cardio-renal affection veronal or other hypnotics must be given with caution, as their excretion must necessarily be delayed, and their accumulation considerably hastened. The following is an instance which came under my care some months ago.

I was called to see the patient (a woman aged 62) in consultation, and found her in a comatose state. She had been suffering from insomnia, the result of anxiety. The diagnosis lay between (1) cerebral hæmorrhage, (2) cerebral tumour, (3) diabetic coma, (4) uræmic coma, or (5) that associated with a drug toxæmia. The patient was well nourished with no obvious gross lesion. There was slight cyanosis; breathing stertorous, and inclined to be shallow; pulse 90, regular, full, and of high tension. There was some slight cardiac hypertrophy. The pupils were both widely dilated; no reaction to light; corneal reflex absent. Knee-jerks absent, and Babinski's sign present in one toe; no ankle clonus. Blood pressure approximately 200-120.

Diagnosis, therefore, rested largely on examination of the urine and blood. No previous history of illness was obtainable. The blood-sugar was 0.133 per cent.; urea 0.033 per cent. The urine was acid, contained 1/10th albumin, 2.5 per cent. urea, specific gravity 1026. Rothera's test was positive. Centrifuged deposit showed only very occasional hyaline casts. Further examination showed albumin varying from a faint trace to a definite cloud, while a week later Rothera's test was still positive and the ferric chloride test negative. A fortnight later Rothera's test was negative and ferric chloride positive. A fortnight later again both ferric chloride and Rothera's tests were negative. A drastic purge and hot packs were given. I also drew 25 oz. of blood from the right arm, and gradually the comatose condition began to subside. The reflexes gradually returned; movement returned to all limbs and body.

Onset of Ophthalmoplegia.—After 36 hours it was noticed that the patient had developed ophthalmoplegia, and hæmorrhages were observed in both eyes. Mr. Ernest Clarke, who saw the patient with me, has sent the following notes:—Jan. 25th: Some ophthalmoplegia still remaining in both eyes, pupils very sluggish and still dilated. The fundi of both eyes presented about the same appearance, viz., papillitis, swelling +3 in the right and +2 in the left œdema spreading from the discs, small streaky flame-shaped hæmorrhages. No sickness or vomiting, and no other symptoms pointing to cerebral tumour. Feb. 6th: General condition better, ophthalmoplegia disappeared, and there was a slight convergent strabismus of the right eye, and pupils were normal but sluggish; the appearance of fundi much the same, except that the swelling was about 0.5 D. less in both eyes. 24th: From this time the patient rapidly

¹ American Journal of Medicine, June, 1907.

improved. June 24th: Both fundi absolutely normal, vision with glasses 6/9. Sept. 23rd: Can now read part of 6/6 with glasses and J.5 well.

In course of time the reflexes became normal and the strabismus disappeared.

The condition, then, pointed to the effects of a drug which, owing to the probable presence of some cardio-renal affection, had exerted a powerful action on the nervous system. It has been noted that in cases of veronal poisoning, nuclear ophthalmoplegia is an occasional concomitant symptom. I therefore suggested that search should be made, and in one of the patient's boxes were found powders of veronal, each containing 7 gr. The patient's mental state improved, though slowly, and after several weeks she informed me that the night before she was taken ill the last thing she remembered was taking two of these powders (14 gr. in all) to give her sleep.

Dr. P. N. Panton, to whom I owe the pathological examination of specimens, thought it probable that the veronal may have been excreted as a carbamide, but it was impossible to determine this fact. I have examined the urine of patients who have taken medinal (a preparation allied to veronal), but have been unable to confirm the above. The patient has apparently recovered, after several weeks' nursing-home treatment. The blood pressure has dropped to 160, and her urine is normal.

I have recorded this case as Mr. Clarke considered the eye condition of great interest and undoubtedly due to the veronal.

Portland-place, W.

A CASE OF ENCEPHALO-MENINGOCELE.

By EMILY G. STUART, M.B. LOND.,
OF QUETTA.

THE following case of encephalo-meningocele in an unusual situation seems worthy of record.

In October, 1923, I attended a Sindhi woman in her third confinement. She had had a normal pregnancy, and both previous children are alive and healthy. This third confinement was quite easy and short, though the patient complained that it was longer than her previous labours. The child, a

girl, was born by vertex presentation, was well nourished and healthy, but had a fluid swelling growing from the nose, and covering the inner side of each eye; the nostrils could be seen below the lower border of the tumour; there was not any nasal discharge, and the baby could breathe through her nose. She could open her eyes slightly and could take the breast and move her limbs naturally. The

From photograph taken immediately before operation.

tumour was lightly bandaged to save the mother's feelings, but on the third or fourth day it had grown larger and was covering the eyes more. I aspirated and drew off clear fluid, after which it was evident that about one-third of the swelling was of solid consistency. The swelling soon filled up again and the anterior fontanelle became prominent. I aspirated the swelling several times, at intervals of two or three days, and after aspiration the fontanelles became less prominent. The tumour was increasing in size in spite of aspiration, and after consultation with Dr. Holland, Major Haughton, I.M.S., and Captain Fry, I.M.S., it was decided to operate.

The operation was performed by Dr. Holland, assisted by Captain Fry, and after incision in the mid-line of the tumour the fluid escaped from a very thin-walled cyst. The sac wall could not be separated from the underlying tissues, so part of the wall was removed and an attempt was made to close the sac, the root of which came from inside the cranial cavity through an opening above the nasal bones. The optic thalami were found to be in the tissue removed. The thin outer skin was sewn up and dressings applied. After five days the wound opened up and fluid oozed through. The child gradually sank and became unconscious and died three weeks after the operation.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

NON-SPECIFIC DISTURBANCES OF HEALTH DUE TO VITAMIN DEFICIENCY.

THE resumed discussion¹ on this subject took place on March 23rd, the President of the Society, Sir ST. CLAIR THOMSON, occupying the chair.

The PRESIDENT, in a brief reintroduction, quoted a letter which the late Sir Clifford Allbutt wrote to the *Times* in his eighty-eighth year in criticism of the white bread usually sold, and calling public attention to the great value of vitamins in food.

The openers of the original debate, Dr. LEONARD WILLIAMS, Lieut.-Colonel R. MCCARRISON, Dr. W. CRAMER, and Dr. G. M. FINDLAY, briefly reminded the meeting of their contentions, the three last-named showing again the slides with which they supported their theses.

Dr. WILLIAM HUNTER said the very able opening by the four speakers had raised the subject beyond the region of mere hypothesis, for it was now clear that when vitamins were withheld from the diet the health of the animal suffered at once, and if this deficiency were continued over a long period actual disease, such as beri-beri, ensued. This lack certainly predisposed to infections of various kinds. He stressed the importance of the lymphopenia as a feature in cases in which there had been deficiency of vitamin B in the food, this vitamin having a direct influence on the blood-forming tissues. The bone changes which Dr. Findlay so well demonstrated were, Dr. Hunter said, identical with the aplastic marrow changes which he had so frequently found associated with what he termed aplastic anæmia, and as a cause of which he usually expected to find some streptococcal sepsis.

Dr. ROBERT HUTCHISON agreed with the discussion being limited to the three accessory food factors A, B, and C. It was contended, he said, that a deficient supply in the food of these specific vitamins was a cause of widespread disorders of health, and mainly the evidence brought was experimental. But it was very difficult to be sure that disturbances of health in animals fed on a vitamin-less diet were solely due to the absence of vitamins, as such diets were usually very abnormal in other respects also. Some were "synthetic" diets, others were deficient in proteins of high biological value, or in a proper balance of the inorganic salts. But granting, for the purposes of argument, that the disorders referred to were usually caused only by vitamin deficiency, was there reason for supposing that disorders comparable to those in the animals experimented upon were being produced by a similar cause in the community as a whole? This he doubted. If the contention of the openers were true, why did not more people show the final link in the chain? In 25 years' work at the London Hospital he had never seen a case of adult scurvy, nor one of beri-beri unless it had been imported from the East. The case of vitamin A, however, was somewhat different, as it was fairly clear that deficiency of this in the diet resulted in interference with growth and a lessened power to resist infections, though there was evidence that at the same time there was a shortage of calorie value in the food given during the growing years. He quoted with approval the following extract from "Food, Health and Growth," by the late Prof. Emmett Holt: "The physician can fall into no greater error than to assume that vitamin deficiency is the chief cause of all chronic nutritive disorders; just as not very long ago these were all referred to auto-intoxication The use of vitamins without definite indications will be popular for a period, but, like other fads, it will pass."

¹ THE LANCET, Feb. 21st, p. 385.

With time and further investigation their true place will be determined."

Dr. J. M. ROWLANDS spoke of his experiences in connexion with pigs on his own farm. He contended that one of the terminal events in the chain of vitamin deficiency was tuberculosis. He had been able to eliminate tuberculosis from herds of animals which previously had been very widely affected with that disease, and he had done it by feeding them on foods known to be rich in the three important vitamins. He held the strong belief that unless cows were fed on such diets, bovine tuberculosis would still be rampant among children, and would increase.

Dr. H. SCURFIELD contended emphatically that there existed plenty of evidence of widespread derangements of health which might be due to diets of deficient quality. It had been shown that intestinal stasis was one result of vitamin B deficiency, and practically the whole nation suffered from constipation. Also there was good reason for believing rickets to be due to defective diet. It was only reasonable to assume that infections could be warded off if the general dietary were improved in the respect alluded to. It had been shown that native races who lived on dairy products and fresh fruit and vegetables were remarkably free from the intestinal disorders which were so common in this country, and the same people were practically free from cancer.

Dr. F. PARKES WEBER said he had seen a good deal of evidence in the East End of London that the terminal link in the chain spoken of by Dr. Hutchison was reached; often it arrived in the form of tuberculosis, and in death from various acute infections. The bad cases were divisible into two classes: those with digestive disturbances, muco-membranous colitis, and visceroptosis, who all suffered from constipation. Secondly, there were those of corpulent body whose terminal stage took the form of cerebral hæmorrhage and arterio-sclerotic disturbances. These had taken excess of food, and perhaps a sufficiency of vitamin, but it had been their undoing.

Mr. ASLETT BALDWIN, referring to Dr. Hutchison's statement that he had never seen in his hospital practice beri-beri or scurvy, said the reason could probably be found in the fact that it would be difficult to find in London a person who was absolutely deprived of vitamins in his food; in that case one could not expect to see end-results which were typical and such as laboratory animals exhibited. He had had some gold fish for a number of years and he fed them on crumbs of whole-meal bread; friends of his who fed theirs on white bread crumbs soon lost them.

The PRESIDENT said that at Midhurst sanatorium as soon as the patients left the dining-room the sparrows flocked in at the windows, and he noticed that whereas they eagerly devoured any butter they could get, they never touched the margarine. It had, in fact, become necessary to cover up the butter after the meal was over.

Replies.

Lieut.-Colonel MCCARRISON, in a brief reply, said Dr. Scurfield's remark about cancer gave him the opportunity of stating clearly what was in his mind on that matter. What he had seen, and what he had said, was that cancer and chronic gastro-intestinal diseases were generally very uncommon amongst certain races in the extreme North of India, races whose diet was extremely well-balanced and rich in vitamins. He had not generalised on this subject because his experience did not go beyond those particular races. He believed it was not a question of civilisation *versus* want of civilisation, or of native races *versus* Western races. For instance, cancer was quite as common in the people of Bengal, whose food was very faulty, as it was now in this country. The important desideratum was that the food should be well-balanced and rich in vitamins and the other essential substances. In the present state of our knowledge—or ignorance—it would be as unwise to disregard the possible action which faulty food might

have as a predisposing cause of gastro-intestinal cancer, as it was at present unwise to assert that faulty food was the cause of gastro-intestinal cancer. A recent report of the Medical Research Council stated that without vitamins normal metabolism was impossible. The Book of Ecclesiasticus said: "The Lord hath created medicines out of the earth; he that is wise will not abhor them." He, the speaker, knew no medicines created out of the earth on which normal metabolism was dependent with the exception of vitamins, and the wise man would not abhor vitamins.

Dr. CRAMER, in his reply, said he thought there should be further experiments from this standpoint on animals which were normally susceptible to tuberculosis. His answer to Dr. Hutchison's criticisms was that one could give the animals experimented on carbohydrates, proteins, inorganic salts, and other substances in due proportion, but if vitamins were omitted the animal died and showed specific lesions. But if animals so deprived were given a little butter, fat or yeast, a dramatic change came over the whole animal in two or three days. The terminal stages of this deficiency were not generally recognised, because they were called by the name of the particular disease from which the patient died, such as pneumonia, though the resistance to that disease had probably been fatally lowered by neglecting to give vitamins. And in some cases, though they had not enough vitamins in their food to keep them in the best health, they might yet have enough to ward off the terminal conditions. The mere fact that cases of beri-beri and xerophthalmia did not occur was no evidence that the people as a whole were taking food sufficiently rich in vitamins.

Dr. FINDLAY, in his reply, spoke of his investigation of an outbreak of pneumonia in an industrial school near Edinburgh. There had been previous outbreaks, and various hygienic improvements were introduced, but without checking the outbreaks. The diet was not thought to be at fault, as it was drawn up by Prof. Haldane. But the speaker found that, in order to save expense, the whole of the food for the boys was put into huge cauldrons, which were screwed down and the food stewed for three or four hours. In previous years there had also been conjunctivitis, which was not cured by applying disinfecting lotions. He recommended to the Scottish Office the giving of cod-liver oil and raw swede juice, and since that was carried out there had been no further outbreaks. In some experiments on animals he found that animals fed on food deficient in vitamins, particularly the A form, quickly caught and died from inter-current infections.

SECTION OF ELECTRO-THERAPEUTICS.

TREATMENT OF CARCINOMA OF THE BREAST BY X RAYS.

A MEETING of this Section took place on March 20th, Dr. STANLEY MELVILLE, President, being in the chair.

The PRESIDENT, in opening the meeting, said the subject was one of great importance, especially at the present time, when, partly from within their ranks, but chiefly from outside it, attempts were being made to divide practitioners of electro-therapy into two camps, the old and the new. This threatened to be a danger to the whole question, and already surgeons were sending patients to electro-therapists with the stipulation that they were not to be treated by so-called "deep therapy." The speaker strongly deprecated such an attitude, as it was undesirable for those in the specialty to become slaves to any particular form of radiation. The researches of Prof. Russ and others, and the various experiments on animals, were an answer to those who said that treatment by the short wave-length was the only one of value. There could be no doubt that high voltage radiation was required, but equally the soft, long-wave radiation was needed. His own view was that too much thought was given to voltage and too little to the other factors.

Dr. GILBERT SCOTT then read a paper entitled

A General Survey of Radiation,

with special reference to treatment of carcinoma of the breast by X rays.

He said he proposed to make a brief survey of the position from three points of view: that of the disease, the therapeutic agent, and the patient. With regard to the disease, he said that when the high voltage technique was published he thought it would prove a short cut to the object, the control of cancer. He particularly avoided using the word cure, when recurrences of so-called cured conditions came after as long as 22 years. A sufficient time had now elapsed since the introduction of the high voltage method for it to be realised that there was still a long way to go. Some said that cancer was a local condition. That might be true within narrow limits, seeing that it was first evident as a local lesion; but it was not safe to plan the attack upon it on this assumption. The surgeon only rarely saw early cases of cancer, the radiologist never. He considered that the development of the primary growth was merely a local indication that the patient had malignant disease; it gave no clue to the extent of such disease. Many schemes had been devised for giving a primary growth its lethal dose, but even when that had been done the patient succumbed in a short time to secondary deposits elsewhere, even though gland areas were irradiated also.

Considering next the therapeutic agent, X rays, he pointed out that the high voltage was a homogeneous technique, the low voltage was a heterogeneous irradiation. These two kinds could not be divorced from each other. The newer methods should be welcomed as an addition to the older, not regarded as their substitutes. Radiation, he said, did not destroy or remove unwanted cells, but the malignant cells were so changed that they were replaced by others, without necrosis taking place, a metamorphosis without cellular death. If such tissue reaction could not be brought about in a particular case, no amount of radiation would destroy the pathological cell. In most cases the pathological cells were replaced by fibrous tissue, not destroyed as when the cautery was used. This meant that radiation produced an indirect effect, and the question arose whether this indirect effect could be utilised on a larger scale. The work of many physicists supported the possibility of liberating for action, by irradiating a large area of the body, some anti-body which was antagonistic to the disease-producing cells.

With regard to the patient, every subject of cancer or other disease must be carefully studied before deciding on irradiation, and an idea formed as to whether curative results were likely to be achieved or only palliative ones.

Dr. Scott said that radiation sickness or malaise was a bugbear to the radiologist. Sometimes this sickness might be sufficient to turn the scale against the patient. It might take the form of vomiting during or shortly after the séance, or the patient might leave feeling well, but in a few hours would feel strange, the stomach feeling upset, or he might have intense headache. In the case of the high-voltage technique the vomiting might become uncontrollable. With low voltage only treatment over a considerable area seemed to cause the sickness, but with the high voltage the sequel followed the treatment of only a small area. He said that during the last 14 years he had used X rays on over 2000 cases of carcinoma of the breast. If the best method of attack in these cases could be decided upon, it would lead well on the road to the successful dealing with cancer as a whole. The primary growth having been removed by the surgeon, the radiologist had not now a tumour to direct his attention to; therefore he had to devise a technique which gave a reasonable chance of destroying cells at various depths and in unknown positions. To prevent recurrences in these cases he considered that heterogeneous irradiation was more valuable than homogeneous. The rays

were absorbed at various depths, and large fields could be covered.

He held that there were objections to the high-voltage technique. The field of radiation was too limited, there was no indication of the depth at which the dose should be delivered; damage to lung tissue in breast cases was comparatively frequent; somewhat serious blood changes were set up. A low-voltage treatment embracing practically the whole trunk seemed to extend the range of control of the disease in a gratifying way. He said he would be glad if speakers would state their experiences on the following points: (1) Reduction of secondary nodules or glands after application of the rays to the primary growth. (2) Cases of skin reaction developing on the side of the body opposite to that irradiated. He had not himself encountered such. (3) Deep or late reactions six months or longer after the last irradiation. He had seen it five years after the last séance. (4) The occurrence of radiation sickness and results of its treatment.

Dr. Scott concluded by showing a number of illustrations on the epidiascope.

Problems in Deep Therapy.

Dr. J. H. DOUGLAS WEBSTER thought three kinds of radiation therapy should be recognised: superficial, medium (to 100,000 volts) and really deep therapy (100,000 to 140,000 volts). Cases of breast carcinoma were best treated prophylactically by medium-deep therapy, with 3 mm. of aluminium and 0.2 zinc. In one series published, 140 cases not too far advanced, 60 per cent. remained free of recurrence after three years. The prophylactic post-operative treatment of breast cancer differed, he said, from that of cancer in most other sites, because of the danger of diminishing the effective lung area and inhibiting the vitality of the pleura by the scattered rays. In breast cases the prophylactic treatment should extend over months. When, during the low-voltage treatment, a small recurrence was detected, the high-voltage technique was substituted, and in a large proportion there had been a successful result, the parts involved becoming normal to palpation. Sometimes the great fatality of breast cancer was forgotten. It had been computed, on the basis of statistics, that a patient with breast cancer and involvement of axillary glands had only a 1 in 25 chance. Lee, of New York, said that only 15 per cent. of patients with breast cancer remained alive at the end of five years. Owing to the large surface involved in these breast cases, and the configuration of the region, combined with the question of the degree of mobility of the arm, the problem of an even irradiation was a very difficult one. It was wrong to divide the area into squares and to irradiate each square, as there was a danger of treating twice the edges of the squares, and missing some parts altogether. The irradiation should be done, preferably, by a near technique over a large surface; his practice was to apply the rays from the top of the neck down to the level of the umbilicus at an angle of 30 degrees, from above, from below, from both sides, and from the back, giving, in some cases, an additional dose to the axillary apex and to the clavicular triangle.

Dr. Webster said he had analysed 335 cases of cancer of the breast treated in the last three years; 148 of these were treated with the medium therapy, but 30 of these could be excluded, as they had only one or two treatments and then left. Of the 118, 34 (29 per cent.) died, 36 were still continuing treatment, and 9 of the 36 were well a year after the operation; 38 were well at the end of two years, and were not now having treatment. This meant that 40 per cent. of the cases showed a good result. Many patients had been treated with high voltage in one part, and in another site with a medium voltage. Of 188 breast cases treated with high voltage, 84 had died, and 45 showed a good result and treatment had been discontinued. In some of the cases in which the surgery was incomplete irradiation produced good results. He contended that each bad result should be carefully investigated, owing to the valuable

knowledge it would probably afford. He described the method of "in advance" prophylactic treatment he had carried out for two years, on the basis of Mr. Sampson Handley's idea of centrifugal spread. It was not of a routine nature; what was done was special to each case. He asked whether there was such a dose of rays as could be called stimulant. Growing seeds could be stimulated by a small dose of the rays. Rays directed to a small tumour on the forehead at once increased the activity and growth of a tumour behind the ear.

The debate was adjourned to a date to be determined.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held at the University, Bristol, on March 11th, Dr. J. O. SYMES, the President, being in the chair.

Dr. R. C. CLARKE opened a discussion on the

Catarrhal Child.

He said that his views were based on extensive observations in children's clinics of several thousand children, and represented ideas that had forced themselves upon him. The subject was one that had not received the attention that it deserved. Only of late years had the routine examination of children supposed healthy been systematically undertaken. When advice was sought only for acute bronchitis or broncho-pneumonia, the significance of preceding bronchial infections might escape notice. Among children between 3 and 6 weeks old, not less than half were already subjects of respiratory catarrh—in the last 1000 cases the exact figures were, 499 with catarrh, 501 without. "Catarrh" was diagnosed on the simultaneous presence of three signs: (a) snuffles, (b) Harrison's sulcus, and (c) definite bronchial catarrh, determined by auscultation. In this connexion, he wished to warn about "snuffles." A nasal catarrh, a napkin rash, and the marasmus which followed inability to suck, from nasal obstruction, must not lead to the (false) diagnosis of congenital syphilis.

When a young infant "caught cold," the first thing that occurred was nasal obstruction. The whole respiratory mechanism was thrown out of gear, for infants refused to breathe except through the nose. Only when half stifled would they open the mouth and breathe through that, so that sleep was disturbed. The drawing in of the lower ribs produced Harrison's sulcus; the latter was a sign solely of nasal obstruction. Rickets might emphasise it, but did not cause it. Since sucking was deficient, feeding became very difficult; if the child did not suck properly, the natural stimulus of the breast was lost, and the breast-milk might go—a disaster of the first magnitude, especially among the poor. The earlier the catarrh affected the child the longer it took to clear up and the greater the certainty that the chest would be affected. If the first "cold" could be postponed till after the sixth month it was practically certain that the chest would escape. But every baby that had nasal catarrh under 4 weeks old (in a series of 400 sufferers) had bronchitis. Further, he believed that once a child became bronchitic it remained bronchitic; every cold "flew to the chest," and it was proper to describe some children of only 6 months old as "chronic bronchitics." As the children grew up the attacks continued; but between the acute attacks there could always be found signs in the chest. The bronchitic baby produced the bronchitic child, and later the bronchitic man—witness the almost invariable presence of Harrison's sulcus in pensioners with bronchitis. Further, he believed that chronic nasal catarrh was the one and only cause of "tonsils and adenoids"; the latter phenomenon was merely a part of the picture of chronic respiratory catarrh. A badly developed nasal organ, leading to deflection of the septum, and a permanently damaged mucosa

leading to chronic sinus disease, were other sequelæ of the same condition. The otitis media which was so very common among school-children was probably only a recurrence of an unnoticed otitis of infancy.

The development of this catarrhal condition depended on two factors: (1) the number and virulence of the organisms reaching the mucosa and (2) the local and general resistance. (1) The amount of infection depended on the presence of persons carrying these organisms, and the lack of ventilation. (2) As to resistance, he did not think the mucosa of the young infant had any power of resistance; and the membrane which had been subjected to repeated infection never gained this power, which was otherwise definite. The very young baby invariably got the whole respiratory tract infected if any part was involved.

Prophylaxis of this condition was not difficult. During the first six months of life every effort must be made to avoid infection. The baby should live in the open air, even in a draught; this rule should not be broken even during the bath. The mother should be examined to exclude chronic *suppurative* rhinitis; if this was found, the use of a mask during the whole time that she was doing anything for the infant was important. The same rule applied to the nurse, though no nurse with a definite nasal infection should be engaged. All visitors should be subjected to the same rule, and never allowed to kiss the child. The parent, nurse, or other children who were carriers presented a difficulty—that is, those who nourished the organisms of disease without manifesting symptoms. As for treatment of older children, this was important because the mucous membrane, if preserved from repeated infection, did recover some power of resistance. Hopelessly infected tonsils and adenoids should be removed. The same general hygienic rules as for infants should be observed; the child should live in the open air; and visits to the cinema and parties should be reduced to a minimum. Cod-liver oil was the only medicine of any value.

The PRESIDENT thought that Dr. Clarke had described an entirely new disease. He had not himself met with this disease. He thought that up to 6 months of age children were extraordinarily immune to infection. The picture they had had presented might be produced by underfeeding, rickets, or teething—all might manifest "catarrh," without there being any infection. He suggested that small children did not readily clear the trachea of secretion, which might lead to râles.

Dr. C. E. K. HERAPATH agreed with Dr. Clarke, but he thought it a disease of the hospital class. As for clearing the air-passages, very young babies sneezed more than adults.

Mr. J. P. I. HARTY believed that infection of the air-passages could take place at a later age than that discussed by Dr. Clarke, especially from parent or nurse. Otitis media was quite common at the very earliest ages. He thought adenoids should be removed at any age, without waiting.

Dr. P. WATSON-WILLIAMS said that the tonsils should not be removed in very young children; these glands had often great value in the fight with infection, and should be preserved as long as possible. Having had many years' experience as a physician, and given especial attention to the chest, he could not agree with the large incidence of bronchitis described. He was interested to hear Dr. Clarke's observations relating to the occurrence of sinus disease in families; he (Dr. Watson-Williams) had had many cases where sinus disease occurring in all the children of a family co-existed with a latent sinus infection—perhaps producing no symptoms—in one or other parent.

Dr. R. A. ASKINS (school medical officer) thought 20 per cent. of all children of school age suffered from adenoids. The prevention of so much sickness was of first importance. Further, bronchitis was very common among the children at primary schools. He had observed the frequency with which the operative treatment of tonsils and adenoids was needed in

all members of a family. He considered that children had some inherited immunity, as regards ordinary infections, which lasted for some months after birth; but this did not apply to catarrhal infections.

Dr. J. A. NIXON thought that though Dr. Clarke's views were extremely heterodox, they drew attention to an important aspect of catarrh. Why should the chronic sequelæ of catarrh occur only in the poorer classes? What factor was concerned other than perhaps feeding? He thought it was very necessary to guard the new-born from loss of heat—was this properly done among the poor? One need never mistake catarrh for congenital syphilis; in the latter the discharge was *purulent*. He agreed that Harrison's sulcus was a sign of nasal obstruction only. Dr. Clarke had omitted the question of asthmatic children, those sensitive to certain proteins; such a condition might lead to bronchitis.

Dr. J. R. R. TRIST called attention to the extreme sensitivity of other mucous membranes in the young child, such as the vaginal. He agreed with the view that young children should be properly protected from loss of heat.

Dr. C. J. C. FAILL pointed out that the tuberculous child was not "catarrhal." If children were to be exposed in all weathers to the open air—i.e., naked—they must have bronzed skin and be well fed—then they did not require clothing.

Mr. A. W. ADAMS pointed out that new-born babies seemed immune from empyema; he thought this could hardly be consistent with such a very high incidence of bronchial infection.

Dr. J. A. BIRRELL asked what was the death-rate among these children. He felt that perhaps Dr. Clarke had mistaken the sounds produced by a flapping soft palate for bronchial râles. Did asthma occur at the age of a few weeks, and was "croup" a condition analogous to asthma? He could not agree that new-born children might safely be exposed to cold.

Dr. CLARKE, in reply, said that he thought the new-born child was infected very readily. Pneumonia did occur in children of this age, and explained some of the cases of "sudden death" in infants. His figures were from four clinics, but all from the lower strata of the population. Catarrh did not confer any immunity, but rather predisposed to a further infection. He had formerly thought that repeated infection was the principal factor in producing the chronic catarrhal child, but now he thought that the *earliness* of the infection was the real deciding factor. Children did not seem to mind the cold, but the poor used much more clothing for their children than the well-to-do. He thought that most cases of asthma in young children were really bronchitic.

Exhibition of Cases.

Mr. H. CHITY showed three cases: (1) Osteomalacia in a girl of 18. Union of ununited fractures of the tibiae followed local injections of colloidal magnesium. (2) Ununited fracture of the tibia, in a child of 5. Local injections of magnesium, and a rib graft, had alike proved ineffectual. (3) Double pleural empyema in a child. Both sides of the chest were opened at the same operation, with perfect result.

Mr. ADAMS showed a case of malignant disease of the thyroid, with secondary glands, relieved by operation; specimens and sections were shown with the case.

Election of Honorary Member.

On the motion of Dr. NIXON, Dr. James Swain was elected an honorary member of the Society. Dr. Swain had been for 25 years a member of the Editorial Committee of the Society's Journal, and for longer a very active member of the Society. The PRESIDENT, in announcing the result of the vote, pointed out that honorary membership was very rarely conferred, there being only two other living honorary members.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF STATE MEDICINE.

A MEETING of this Section was held in the Royal College of Physicians of Ireland on March 13th, Dr. N. M. FALKINER, the President, in the chair.

Dr. BRIAN CRICHTON read a paper on

Infant Mortality.

He compared the infant mortality rates of various English towns with that of Dublin (125). To produce a healthy child, healthy parents, healthy surroundings, and good food were necessary. The greater portion of the centre of Dublin was hygienically bad and to be condemned. Not more than 50 persons should be allowed to live on each acre, but in some wards in Dublin the number per acre was as high as 117 or even 138. Dr. Crichton then outlined a scheme for the improvement of child life in Dublin. Use should be made of the existing maternity hospitals in Dublin, the Rotunda, the Coombe and the National Maternity, to which mothers have been accustomed to go for advice. Attached to these there should be welfare centres, both antenatal and postnatal. At these the mothers could be advised as to the health and feeding of their children and food could be supplied at as near cost price as possible. Almoners and specially trained district visitors could go from these to visit the infants in their homes. These centres would also be very useful for the training of students and nurses. As regards older children, he pointed out the need for special schools for mentally deficient children and also for open-air schools for delicate children. In concluding, Dr. Crichton referred to the death-rate among illegitimate children, which was six times that of legitimate children.

Sir JOHN MOORE emphasised his belief that it was the bounden duty of every mother to feed her child during the first nine months of the child's life, and he thought this was a duty which was very often disregarded. Sometimes, of course, it was impossible for the mother to feed her child, but the natural food for an infant was the mother's milk. Recently there had been a great practice of feeding children with milk which was contaminated, or with preparations of milk which were very often probably poisoned.

Prof. J. W. BIGGER drew attention to the position regarding infantile mortality in Ireland compared with that in England. The mortality in Ireland in 1923 in the Free State was 66 per 1000, while in England and Wales it was 69 per 1000. Therefore Ireland was in a rather better position than England and Wales. He felt that Ireland at present was contented with her position, because it was said that the Irish infantile mortality rate was much less than anywhere else, and so nothing was done to get it still lower. It had been recognised in England and Wales since 1904 that the rate there was too high, and steps had been taken to bring it down, and had been successful. If this had been done in Ireland, the rate in 1923 should have been only 47 per 1000, instead of 66 per 1000. Premature births, he said, were accountable for about 6 deaths out of every 1000 births, and if the scheme which Dr. Crichton had outlined, of setting up pre-natal schools in connexion with the maternity institutions in Dublin could be brought about, he thought that a great many of these deaths could be avoided.

Dr. R. H. MICKS referred to the number of sickly wasting children who had come to general hospitals and whose parents thought they could be cured in a week, whereas they could not even be cured in a month, for it sometimes took several months to effect any improvement in their condition. Really bad cases of marasmus took a year to cure. He referred to the danger of the "tuberculosis houses" of which there were so many in Dublin, and the number of children suffering from tuberculosis, which was probably due to the unhealthy state of their

surroundings. This was not the fault of the parents, for no better houses were obtainable.

Prof. J. T. WIGHAM said that it had been asked why infant mortality should be avoided, since an easy way of limiting the population was for children to die soon after birth. It had been pointed out that at present there was a great excess of unskilled labour, and a great many of the town-born children grew up as unskilled labourers. He thought that the answer to such a question was that infantile mortality was an index of children's disease, and that a great many children who did survive from disease in childhood were unfitted to be proper citizens.

Dr. W. D. O'KELLY, Dr. N. M. FALKNER, jun., Dr. P. DE BURCA, and Dr. KENNEDY CAHILL further contributed to the discussion, to which Dr. CRICHTON replied.

PLYMOUTH MEDICAL SOCIETY.

At a clinical meeting of this Society, held at Beaumont House on March 17th, Mr. C. L. LANDER, the President, showed a case of splenomegalic polycythæmia of many years' duration.—Mr. H. F. VELLACOTT showed a tumour of the lower part of the thigh in a man aged 27, who gave a history of six years' duration. A cystic tumour had been removed elsewhere two years before. It was generally held that the present condition was sarcomatous, and such it appeared to be to the naked eye on examination of a fragment removed next day for microscopic report.—Mr. C. M. KENNEDY showed two cases: (1) A young man with an ulcer of the tongue suffering, in addition, from tuberculous epididymitis and chronic phthisis. It was an example of the solitary tuberculous ulcer of the tongue. (2) An old man with a mass in the back of the tongue, not ulcerated. The glands beneath the jaws were extensively involved. The history extended over a month; Wassermann negative. This was probably an epithelioma, and not inflammatory.—Mr. J. R. ROLSTON showed the eyes of a child, aged 10 months, removed on account of gliomata growing from both retinae.—Mr. EDRIC WILSON showed a man suffering from hypertrophic biliary cirrhosis, bronzed, with large liver and spleen. He showed also the plates of a case of Perthe's disease and outlined the treatment of this condition of the hip-joint, which formerly was taken to be tuberculous. It was probably of the nature of a mild staphylococcal infection, and had to be differentiated from slipped epiphysis and osteo-arthritis of a juvenile type.

The PRESIDENT read a note on the relation of herpes to chicken-pox.—Dr. J. RIDDEL read the notes of a case of puerperal septicæmia which recovered after many rigors with temperature 107° F. The uterine condition quickly settled down after a large-sized tube had been placed in the uterus to allow of frequent eusol irrigations, but septic thrombosed piles seemed to provide the source of infection which led to the rigors with hyperpyrexia. Blood cultures were negative.—Mr. HAMILTON WHITEFORD read notes of 11 cases collected from the literature to illustrate the results of the operation of lymphaticostomy as practised by Costain. It was possible to trace four recoveries and three deaths, and the operation appeared to be worthy of further attention, though it seemed, at first sight, strange to operate in the neck to cure a pathological condition of the abdomen.

TWO YORKSHIRE HOSPITALS.—Princess Mary has opened the King Edward VII. Memorial Wing of Pontefract General Infirmary free of debt, the whole of the £12,000 which it has cost having been subscribed. The wing contains two wards, each of which will accommodate 12 patients; there is, in addition, a small private ward of three beds. During 1924 the out-patients at Batley and District Hospital increased by nearly 1000, and £24,000 is about to be spent upon extensions and improved equipment.

Reviews and Notices of Books.

A SYNOPSIS OF SPECIAL SUBJECTS.

Diseases of the Skin. By H. C. SEMON, M.A., M.D.
Obstetrics and Diseases of Women. By MALCOLM DONALDSON, M.B., B.Ch., F.R.C.S.
Diseases of the Ear, Nose, and Throat. By ARCHER RYLAND, F.R.C.S. Edin.
Diseases of the Eye. By J. F. CUNNINGHAM, O.B.E., F.R.C.S. London: H. K. Lewis and Co. 1924. Pp. 376. 18s.

THIS handy volume will undoubtedly receive a warm welcome from the busy practitioner, and will take its place on his shelf beside the well-known companion volumes of Tidy, Hey Groves, and Wheeler and Jack.

The authors state in their preface that their work "cannot be commended from the literary or educational point of view. Its aim is practical." The practical aim is not one to be deprecated, and the need of the average medical man in special subjects such as these is primarily for some reliable condensation of modern knowledge that will help him to accurate diagnosis and immediate treatment. The conduct of a long or serious disease or major operation in special regions is not usually carried through without consultant advice, and too much detail in a text-book is both superfluous and irritating to the busy man. The error here lies, perhaps, in over great condensation; the sections headed "treatment" are in some cases disappointingly brief. The practitioner who relies wholly on this book for information as to the management of such common complaints as acne and pruritus, for instance, will find himself at the end of his resources sooner than he need be. The subject of dermatology is, in the present state of our knowledge, so difficult that the practitioner would be grateful for ample variety in the possible treatments to be applied, and for rather more definite guidance as to the length of time that must be allowed to elapse before a change may be anticipated.

The section on obstetrics is particularly up-to-date and adequate, considering its condensation, and to those who desire a synopsis of this subject can be cordially recommended. It seems open to question, however, whether it is wise to include this difficult subject in such a book. It is a part of medical practice in which the average doctor is rightly expected to be more competent than in the other "special subjects." He should not be encouraged to acquire a smattering, and he is not in the habit of calling in specialist advice for any case which deviates from the normal. His acquaintance with the varieties, dangers, and treatment of normal and abnormal childbirth, therefore, ought to be extensive, and a synopsis, however excellent, may not help him much. The gynaecological part of the book is less satisfactory than the obstetric; it gives the impression of having been written from the point of view of a gynaecological surgeon rather than that of the practitioner. The word "leucorrhœa," for instance, does not occur in the index, yet its colloquial equivalent is ever on the lips of the patient. The great need of the practitioner is for some advice on the management of such symptomatic disorders. Again, there are many psychological and domestic factors in sterility which should be investigated before the patient is "examined thoroughly from head to foot" or oxygen is passed through the cervical canal, but these preliminary considerations are not mentioned. In the treatment of dysmenorrhœa there is no reference to the use of antipyrine and caffeine or the endocrine preparations, while the frequent psychological factor is completely ignored. The only treatment suggested for senile endometritis is the application of radium. These are the considerations which present themselves in the consultant's house after the ground has been cleared for him by the less elaborate or "common-sense" procedure of the local doctor, but for a practitioner who is not sufficiently experienced to do these things without the

aid of a "synopsis" there should be some reference, at least, to the part he has to play.

Such criticisms cannot be directed against the two other sections—viz., those on diseases of the ear, nose, and throat, and the eye. Here particular attention has been paid to the points which are of importance in the earlier stages and simple everyday management of the conditions dealt with. The treatments are given with full practical detail and, in the former section, with plenty of actual prescriptions, which are always a welcome sight to the young practitioner. The ground covered is extensive, but the condensation is adequately carried out, room being found for such matters as geographical distribution, ætiological theories, comparative tables of diagnostic symptoms, and valuable cautions as to the use of certain forms of treatment. These two sections alone would make the book a sound investment, and there is a great deal in the section on obstetrics which is of value. A minor fault of production which is somewhat irritating to the reader is the use of too thick capitals for the headings of "Diagnosis," "Treatment," &c., which causes these to stand out more clearly than the varieties of disease which are being considered. This makes it difficult for a searcher to find quickly the point desired.

The compilation will assuredly be welcomed.

THE LIFE-STORY OF THE ADDER.

By NORMAN MORRISON, F.Z.S. Scot. Paisley : Alex. Gardner, Ltd. 6s.

FROM Bible story down through mythological legend, mediæval therapeutics, and folk-lore to Freudian interpretations there are many evidences how deeply the snake family has interested mankind. No doubt the danger of snake-bite has much to do with this, and, even in our island, there are plenty of instances (one is recorded, for example, in THE LANCET of March 14th) that such an accident may be no trivial matter. In themselves, however, these creatures are well worth careful study, and Mr. Morrison, in this unpretentious but most interesting little book, has rendered a real service to natural history. We can never have too many students of his kind, who devote themselves to the observation of the living animal.

Those of our readers who practise in the country will add one interest more to their walks if they submit themselves to the spell of this book.

LOUIS PASTEUR.

By S. J. HOLMES, Ph.D., Professor of Zoology in the University of California. London : Chapman and Hall. Pp. 246. 7s. 6d.

Prof. Holmes, in his preface, says that he makes no apology for adding to the number of books upon Pasteur. We fancy that some is needed. Apart from the Life, by Vallery-Radot, we do not know exactly how many shorter accounts have been published, but the field in English seems adequately filled by the admirable American version of Duclaux and by Descour, which has been translated by the Wedds. If the present account had any new facts to bring out, or if it looked at the subject from any new point of view, there might be something to be said for it, but it is, as the author says, just a brief and simple account of Pasteur's methods and his chief discoveries such as has been given again and again. It fails, too, as others have failed, to bring out Pasteur's real importance which is, not that he made human life more convenient by teaching Frenchmen to make as good beer as Germans or by discovering a cure for hydrophobia, but that he persuaded the world to believe that bacteria were of importance and not merely the objects of curious interest they had been since Leeuwenhoek first clearly described their appearances. Let it be added, too, that Prof. Holmes follows his

predecessors in easily falling into a vein of hyperbolic exaggeration; talking of the relations of Pasteur to the Academy of Medicine, he says (p. 156): "Little did his medical colleagues then realise that they were dealing with a man whose discoveries with regard to disease were to be of greater value than those of all the academies of medicine in the history of the world," which is a nonsensical comment on the natural and desirable scepticism with which Pasteur's views were at first received. A cult pursued in this vein finds its suitable goal in canonisation; it is out of place in scientific biography.

THE WEBER COLLECTION.

Vol. II. Macedon, Thrace, Thessaly, North-Western, Central, and Southern Greece. By L. FORRER. London : Spink and Son. 1924. Pp. 579. With portfolio of 102 plates. £3 3s.

THE first volume of Mr. Forrer's catalogue describing the Greek coins collected by the late Sir Hermann Weber, M.D., was reviewed in THE LANCET in 1923 (i., 199). The splendid second volumes of text and plates which Mr. Forrer has now produced deal with that part of the collection comprising the cities of European Greece from Thrace and the Euxine to Peloponnesus, together with Crete and the islands of the Ægean Sea. Nearly 3000 coins are here described, including many individual specimens of outstanding merit and interest, and a number of unusually full and important series of the coins of a particular mint. There are, for example, 150 coins of Athens (including three specimens of the later gold coinage), 175 coins of Corinth (with important specimens of the earliest coinage), 82 coins of Elis, of which no less than 47 are staters, the highest denomination of the silver coinage of this mint and among the most treasured of ancient coins for their supreme artistic merit. Of less importance are the 39 coins of the Thracian Chersonese, but it may be noted that no less than 14 varieties were not to be found in the British Museum collection to which they have now passed. The coinage of the kings of Macedonia, the interesting early coins of the wild Macedonian tribes, the coins of the kings of Pæonia, and those of Thrace in general are all well represented. There are many beautiful specimens of the coinage of the Thessalian towns where, except in a few cases, the output was never large.

Among the more important individual coins may be noticed three staters of Amphipolis with the famous type of the full-face head of Apollo, a unique stater of the Acarnanians struck at Eniadae and showing figures of Apollo and Herakles, an example of the famous staters of the Amphictyonic Council, probably struck for the Pythian festival in 346 B.C., after the Phocian War, the stater of Arcadia with Pan seated on a rock, and the beautiful stater of Pheneus showing Hermes running with the child Arkas. There is also a drachm of Pheneus with Hermes seated on a rock. The more important gold coins include a stater of Panticapæum and the half-stater of Pyrrhus, King of Epirus. Among rare Thessalian coins may be noticed the didrachm of the Cetai with the lion's head and Herakles for types as on the commoner smaller denominations. There are fine specimens of the rare but better known silver coins of Abdera, Ænus, the Chalcidic League, Larissa, the Opontian Locrians, and Messenia. Two large coins of Dicæa, weighing 283 and 150 gr. respectively, with the usual type of a head of Herakles as found on the smaller coins, call for special mention, as does the tetradrachm of the Thracian Chersonese with a lion and an archaic head of Athene for types. With this coin may be classed two very rare coins assigned by Mr. Forrer, with a query, to Olynthus. Both show on one side a quadriga viewed from the front: for the other type one has an irregular pattern, and the other, the only specimen known, a male head. Mr. C. T. Seltman, in his recent work "Athens: Its History and Coinage," assigns all these coins to the Athenian tyrants—Miltiades I. and his nephews Stesagoras and

Miltiades II., who made themselves lords of the Thracian Chersonese during the period 559-493 B.C.

It has been stated that Sir Hermann Weber's interest in ancient coins was "first roused by types referring to the healing art." In this connexion one naturally turns to the coins of Epidaurus, where the types refer to the worship of Asklepios. No. 4223 is an example of the very rare drachms of Epidaurus, which have for types on one side a head of Apollo, the father of Asklepios, and on the other, Asklepios seated on his throne with his right hand extended over the head of a serpent. Beneath the throne is a dog. As is well known, a kind of faith-healing was practised at this place. The sufferers slept in the sacred shrine and the god manifested himself to them in their dreams. It would appear from the record of the "cures" which have been left on inscriptions that sacred serpents and dogs were kept in the shrine and were supposed to heal the sick by licking them. Examples of the "cures" are given by Dr. Singer in his interesting chapter on Greek medicine in the volume of essays, "The Legacy of Greece," published in 1922 by the Oxford Press. Other coins show Epione, the wife of Asklepios, and the instrument known as the cupping vessel occurs as a symbol beside the main type. The cupping vessel is a type found elsewhere, at Astacus in Acarnania and, with forceps, on coins of the Thessalian town Atrax. Thessaly was another centre of the worship of Asklepios and was the home of Cheiron, the wisest of the Centaurs and renowned for his skill in medicine. At Tricca, the legendary birthplace of Asklepios and mentioned by Homer as subject to his sons Podaleirios and Machaon, the doctors of the Greek army at Troy, was the oldest of all the temples of Asklepios in Greece. On the coins of Tricca appear an interesting type of Asklepios feeding his sacred serpent with a bird. A similar type appears on coins of Larissa and Magnetes. It is perhaps appropriate that the most famous of ancient sufferers, the hero Philoctetes, had his home in Thessaly, though it will be remembered that his pains could not be alleviated by the medical skill of the time, and his cries so distressed the Trojan host that he had to be marooned. Philoctetes is shown on the coins of his native town Lamia. Specimens of all these coins are to be found in the Weber collection.

It only remains to add that the publication has been carried through by Messrs. Spink and Son in the same lavish way as was the case with Vol. I., and that Mr. Forrer is to be congratulated once again for the care with which he has described the coins. There is only one place where what seems to be an error can be noticed. No. 3140, a coin of the Opuntian Locrians of the period before 338 B.C., has been re-struck; according to Mr. Forrer the original coin was "apparently a Syracusan tetradrachm." But the piece weighs 184 gr.—i.e., it is of Æginetan weight, as would be expected for Locris, while if it had originally been a Syracusan tetradrachm the weight would be c. 260 gr.

JOURNALS.

SURGERY, GYNÆCOLOGY, AND OBSTETRICS. Vol. IX., No. 1.—Basic Principles and Supreme Difficulties in Gastric Surgery. A survey of the end-results of the various operations of gastric surgery is given by H. B. Devine in a series of 1000 cases. Evidence is produced to show that a good result is only achieved if regurgitation is established, no matter whether the operation used be a simple gastro-enterostomy or a partial gastrectomy, and it is suggested that as the former procedure does not always succeed in accomplishing this object, partial gastric exclusion may be used with less risk to the patient than partial gastrectomy, with equally good results. It is thought that this procedure by partly cutting off the sympathetic supply to the stomach alters its tone and so allows of better regurgitation.—

L. R. Whitaker and G. Milliken: A Comparison of Sodium Tetra-Bromphenol-phthalein with Sodium Tetraiodo-Bromphenol-phthalein in Gall-bladder Radiography. As the iodine salt is nearly twice as opaque as the bromine to X rays and the toxicity is shown to be about equal, it appears that the iodine salt is the better. The author's experiments confirm their suggestion that this is so.—Margaret S. Witter: Post-operative Leucocytosis. The author gives the result of careful post-operative leucocyte counts and shows that there is a leucocytosis which reaches an average maximum of 18,000 four hours after operation and returns to normal by the fifth day.—R. W. McNealy: The Place of Electrol Vein Ligation in Blood-vessel Surgery. Simultaneous ligation of both artery and vein of a limb is less likely to be followed by gangrene than ligation of the artery alone. Cases are quoted showing that in threatened gangrene the vein may be ligatured as a therapeutic measure in selected cases.—C. W. Rand: Tumour of the Left Gasserian Ganglion. A report of a case of endothelioma successfully removed at operation.—R. H. Jackson: Extensive Resection of the Small Intestine in an Infant. There is some doubt as to how much of the small intestine may be removed without seriously affecting the nutrition of a child. A case is reported in which 4 ft. 8 in. of the lower part of the small intestine was resected in a child of 2 years. This is thought to be about 2/5ths of the total in a child of this age. This child is now 9 years old and is of normal weight and development.—F. M. Pottenger: Pain from Pleura Simulating that from Abdomen. It is shown by a consideration of segmental nerve distribution that pleural injury may give rise to pain simulating that of an abdominal lesion.—Richard Lewisohn: The Frequency of Gastro-jejunal Ulcers. In the writer's series gastro-jejunal ulcers developed in 34 per cent. of gastro-enterostomies. Partial gastrectomy is advised to cure these cases, and it is suggested that if performed in the first instance it would prevent them.—W. H. Goeckerman: The Effect of Surgical Trauma in Patients with Syphilis, with Special Reference to Healing of the Post-operative Wound. Although it is advisable that syphilis should be treated before operation, evidence suggests that the tissues of the syphilitic heal as well as those of the non-syphilitic patient.—Howard K. Tuttle: The Treatment of Abortion. The question whether early operation or expectant treatment in abortion gives the better result remains doubtful. In this article the results of early operation in all cases (1164) are given, and show that under hospital conditions the results of this treatment are similar to those given in recent papers advocating the expectant measures. In selected cases expectant treatment is advised.—Hugh H. Young: The Treatment of Infections, General, Local, and Urinary with Intravenous Injections of Mercurochrome. A review of 255 cases in which mercurochrome injections were used convince the author of its value. Various cases of septicæmia, pneumonia, and encephalitis are quoted, many of them severe, in which rapid recovery followed. The dose used varied up to a maximum of 7 milligrammes per kilo. 75 per cent. of the patients recovered and of these results 42 per cent. were thought to be due to this drug. Severe reaction occurred in 28 cases and two patients died soon after an injection.—The department of technique is largely occupied by two articles on the Treatment of Fractures of the Femur by H. E. Conwell and Mrs. Langworthy.

ERRATUM.—A commendation to our readers in THE LANCET of March 14th of a small book on "Pernicious Anæmia and Aplastic Anæmia," written by Dr. Arthur Sheard, unfortunately stated the name of the author wrongly. We are sorry that Dr. Sheard's useful contribution to a difficult subject should have been credited in the wrong place. The book is published by John Wright and Sons, Ltd., Bristol.

THE LANCET.

LONDON: SATURDAY, MARCH 28, 1925.

THE MEDICAL CURRICULUM: AN INTERNATIONAL SURVEY.

EVERYONE who read with interest Mr. ABRAHAM FLEXNER's first critical account of medical education in Western Europe and America 12 years ago will welcome his new volume,¹ in which he re-surveys the field. Apart from the writings of Sir GEORGE NEWMAN, the debates at the General Medical Council, and the consequent articles and reports in our own columns, there has been little said on the general bearings of the medical curriculum, either in this country or elsewhere, before his first report. It was consequently something of a revelation to many people that there was so much that wanted saying on the subject and so many problems to be discussed and, if possible, solved. There has indeed been a troubling of the waters since, and the widespread reforms achieved in America have brought home to us on this side healthy doubt as to the perfection of our own methods and results. Twenty years ago there were in the United States about 400 schools producing qualified medical men; four or five were good, a few mediocre, the rest ranged from pretty bad to scandalous frauds. There are now about 90; almost all might fairly be called good, while ten or a dozen reach a level which in most respects is not bettered elsewhere. In our country the situation was, of course, different; there was nothing scandalous enough to attract attention, but Mr. FLEXNER draws attention to a good deal which in the natural course of development has come to be inadequate and out of date. We are not prepared to agree with Mr. FLEXNER always, but every thinking medical man must be grateful to him for the stimulus of his visits and the help which his critical discussions have given to those who believe that the excursions and alarms in our own medical schools in recent years have been properly directed to the ventilation of questions which needed consideration. Grateful, too, should we be for the restraint which has reduced to a moderate and most readable compass the results of repeated visits to many of the chief medical schools of Western Europe and America; we doubt whether there is a word for each mile that must have been travelled. To those for whom science consists in reducing facts to numbers, considering the possibilities of the subject, the volume will seem about as unscientific a product of such an inquiry as one could imagine; for Mr. FLEXNER gives hardly any statistics. But all engaged in medical education will be grateful for the work, and many will be grateful for the lack of percentages.

Mr. FLEXNER's book covers broadly two topics. It describes the facts as they are now in relation to what they were 15 years ago, and it discusses the theory of medical education with the object of discovering the best possible method of achieving it. Easy reading as it makes, it is closely written and no summary of the facts is possible; those who are not familiar with them will find much food for thought

in the fundamental differences of ideals and methods which characterise French, German, and British practice. And on the theoretical side we must equally urge our readers to resort to the original for an adequate appreciation of Mr. FLEXNER's conclusions. In taking up certain of his points which are of particular interest to ourselves, let it be pointed out that no attempt is made by the author to value the relative virtues of the different methods of education, which he exposes, by measuring the efficiency of their products in terms of the work-a-day medical man. Whether the practitioners trained in didactic clinical French schools are any more or less fit to take care of their patients than those brought up in the German university clinics, or in the practical British schools, is apparently regarded as being either beside the point or an insoluble point. Insoluble it almost certainly is, and if the facts could truly be ascertained we could not fairly attribute any demonstrable contrasts to differences in the medical curriculum without being sure that the curricula were brought to bear on similar material. Which they are not. And Mr. FLEXNER is right in arguing the matter from general principles rather than by embarking on what must necessarily have been an unconvincing direct comparison of results. He has a complete faith in the ideals of university education; better education cannot fail to produce a better product. And what he has to say will appeal with less cogency to those less well equipped in that faith. His main argument is roughly this. Medicine is a science or so near a science as makes no difference. Whether it is called an art, or a science, or an empiric art making its way towards becoming a science, it has accepted the fundamental criteria of a science and has pledged itself to the critical scrutiny of facts, thus adopting the scientific spirit and aim. It is therefore best studied in the way which has proved most successful in other sciences—i.e., for its own sake and by people whose sole concern is with the advancement of knowledge by teaching and original inquiry. As examples of success the German universities in the third and fourth quarters of last century are the most conspicuous; physiology in our own country is also an obvious model. Medicine should, it is argued accordingly, be treated in the university spirit and by the university technique, and the ideals of its teachers should be identical with those which vivify zoology, philology, or mathematics. If these general principles are to have effect in medicine, it is obvious that a good many of the medical schools in America, all of those in this country, and still more markedly the French establishments, require considerable revision. Dealing with our own schools in regard to clinical subjects, we note that Mr. FLEXNER criticises the schools in the following ways. The hospitals, which are the necessary laboratories of the clinical staff, are not under university control; they exist primarily for the treatment of the sick poor and not for teaching and investigation; though good-will and common-sense may effect a fair compromise, the two objects are by no means always compatible; the heterogeneous collection of diseases, for example, which is desirable for under-graduate teaching is most unsuitable for investigation and may make real investigation impossible; the selection of cases on the test of illness and poverty is not what a university school would choose as the best procedure. On the question of staff, he is quite definite that the "whole-time" system can alone achieve the best results, and that the arrangement by which professors of medicine may have their main preoccupation in private practice is incompatible with university ideals. "Whole-time" is perhaps rather an unfortunate

¹ Medical Education: A Comparative Study. By Abraham Flexner. New York: Macmillan Co. Pp. 334. 1925.

expression; it means not that a man should spend his whole working time in the business of his wards and laboratories, but that his real absorbing interest in life is the progress of knowledge, and that he should be relieved of the necessity of earning his living in a competitive professional life in order that he may freely exploit his passion. In other words, the "whole-time" ideal is reached by having the right spirit, not the correct time-table. And in the presence of the right spirit the details may work themselves out in a variety of ways. The professor must indeed be "whole-time" in fact; even that is far less than he needs for his own education. And if he thinks he can profit by seeing private patients, let him do so by all means so long as he has no pecuniary interest in his consultations. Of his assistants some may be whole-time, some may be part-time; the right spirit again will be able to bring into useful coöperation a varied and varying collection of human instruments; enthusiasm is more than organisation. Mr. FLEXNER criticises severely the sad in-breeding habit of our schools—a habit which, it seems, prevails in America as well and is almost unknown in the Germanic countries. Other things being equal, the scale ought to be against the local man rather than in his favour; a wider horizon, a different training, a fresh outlook, are worth more than the clubbable qualities which sometimes determine appointments.

Such are some of the comments which are passed on our own methods of conducting medical studies, which, based on an entirely different ideal, have aimed at producing men ready for practice. This, Mr. FLEXNER urges, is impossible; the medical school cannot expect to produce fully-trained doctors; it can at most hope to equip students with a limited amount of knowledge, to train them in the method and spirit of scientific medicine, and to launch them with a momentum that will make them active learners for years to come. And yet with a curious flair, on which he comments in another passage, Mr. FLEXNER judges that our actual clinical teaching is probably the soundest in the world. Its merits are great and obvious: "they are" (we quote) "fully appreciated by the British themselves and not unappreciated in other countries." But this excellent finish he finds to be applied to ill-prepared and unsuitable material, for the standard of general education necessary for admission as a medical student is lower than anywhere else—lower on paper than in America, and lower in fact than on the Continent. Medical education, we agree, cannot be for everyone: it is too exacting; the ill-taught and badly-trained schoolboy cannot legitimately find a place in it with advantage to himself or the public. When the student passes from school to college to begin his specialised career, he is apt to be met with an *ad hoc* conception of the medical sciences which is wholly mistaken and short-sighted. "Anatomy, physiology, and pathology are sciences as such, just as they would be if it had never occurred to anyone to include them in the medical curriculum," says Mr. FLEXNER, and if they are not cultivated in a broad university spirit as legitimate objects of human curiosity they will be sterile. If, as is often said now-a-days, they must be presented from a medical aspect to arouse the interest of the student, the remedy is to change the student. Mr. FLEXNER, therefore, would have us believe that our ideals and methods need examination and perhaps revision, while his remarks on the curricularisation of American education, the mediæval French procedure, and the didactic clinical teaching in Germany will give warning of many, perhaps unsuspected, fires to those who want

to get out of their own frying-pan. And, if we have emphasised his criticisms, let it be realised that he is always constructive both in urging on everyone the ideal which he serves and in indicating the practical details through which it may be served. After all, as the cover of the book reminds us, medical education is not medicine but education—and it is at least possible that this point of view has been rather overlooked. Few, perhaps, will go with Mr. FLEXNER all the way at once: everyone who has to do with medical education will be well advised to listen to what he has to say in his valiant effort to raise the profession to higher levels.

THE INTERPRETATION OF PULMONARY RÂLES.

IN the course of a survey of the Union of South Africa, undertaken by the Union Department of Public Health with the object of obtaining information about the incidence of tuberculosis among native races, attention was drawn to an interesting clinical condition known as "defective lungs." By this term is meant, in the great majority of cases, a condition in which characteristic fine, crepitant râles are detectable in the marginal areas of the lungs of natives who otherwise appear to be perfectly healthy. That it is of some importance is shown by the fact that it was detected in 2679 out of 76,534 natives recruited for work in the gold mines. The peculiar conditions of the Rand mining industry make it highly undesirable to employ any individual about whose pulmonary health there may be the slightest doubt, and these natives have hitherto been rejected by the mine medical officers. In view of the fact, however, that the last word as to the interpretation of physical signs has not yet been spoken, it was decided to conduct an investigation into the significance of these particular signs, and the results of this inquiry have been published by Dr. W. WATKINS-PITCHFORD and Dr. PETER ALLAN.¹

The investigation was conducted with characteristic thoroughness. 111 natives were chosen as typical examples of this condition and were submitted to a complete physical examination. They were kept in hospital under observation for an average period of five days, pulse, temperature, and respiration records were made, the sputum and urine were examined, Wassermann and von Pirquet tests carried out, and radiographs taken of the chest. A complete clinical picture having thus been obtained, the individuals were then drafted to one of the mines. While on the mines the natives underwent special clinical examinations once a month, and at the end of the period of the experiment, varying from 6½ to 2 months, final examinations were made at which radiographs of the chests were again taken. Five months after the experiment was concluded the records of the subjects were examined to see whether any had developed tuberculosis or tuberculosis with silicosis. The data supplied in the paper are, as is usual in the publications of this Institute, very complete, and the conclusions drawn from them are of interest not only to the industrial medical officer but also to the general physician. It is concluded that these râles are a physiological peculiarity rather than a pathological manifestation. In some cases—28 per

¹ An Investigation into the Significance of Localised and More or Less Persistent Râles in the Marginal Areas of the Lungs of Apparently Healthy Natives. By W. Watkins-Pitchford and Peter Allan. Publications of the S. African Institute for Medical Research. 1924.

cent. in this series—they may possibly be due to demonstrable inequality in the movements of the two sides of the chest. But in all cases they are believed to be of pleural origin, due to abnormalities in the supply, distribution, or removal of the natural lubricating transudate of the membranes. They may coexist with tuberculosis or silicosis, but are not specially indicative or prognostic of these diseases. But they may, on the other hand, obscure the auscultatory signs of tuberculosis, and it is of paramount importance, therefore, that all labour recruits presenting this condition should be submitted to X ray examination.

While this investigation is of immediate importance to the Rand mining industry, its general significance should not be lost sight of. Until it is possible to record physical signs in the same way as it is possible to record a pulse tracing, or to demonstrate abnormalities in the renal secretion, every physician must judge for himself the degree and extent of abnormal pulmonary and cardiac sounds. He must establish for himself the standards by comparison with which he may determine the significance of physical signs. He is, in fact, himself the variable, the experimental, or instrumental error in the observation of his patient, and it is only by careful and controlled work that he can so reduce the margin of error as to raise his technique from an art to a science.

THE NEW PUBLIC HEALTH BILL.

A MONTH ago the Minister of Health announced in answer to a question in Parliament that he hoped to introduce a Public Health Acts Amendment Bill on the lines of the legislation of 1890 and 1907, embodying for the benefit of the whole country various provisions at present contained only in local legislation. The Government Bill is known to be in an advanced stage of preparation, but there is scant hope of its introduction this Session. Fortunately a private Member's Bill, drafted with a similar object, has turned to good account the opportunity of a Friday afternoon debate; at the end of last week it secured an agreed second reading with the assent of all parties, the support of the Association of Municipal Corporations, and the blessing of the Ministry of Health. Mr. WOMERSLEY's Bill, the terms of which are outlined this week by our Parliamentary Correspondent, will do three excellent things. It will lighten the burdens of progressively-minded ratepayers, who will no longer have to pay the heavy cost of promoting special legislation to obtain the public health facilities which other local authorities enjoy; it will ensure a measure of administrative uniformity throughout England and Wales; and it will save valuable Parliamentary time. We have more than once commented on the repeated recommendations in the annual reports of the Local Legislation Committee in favour of the passing of such a Bill. One other admirable consequence will be the fact that the way will thus be cleared for the re-casting of our public health law into a single, orderly, comprehensive, and comprehensible code,—a matter which the then Minister of Health admitted to be of urgent importance two years ago. It is almost inconceivable to think that our principal legislation on the subject was passed as long ago as 1875, and that it has undergone no substantial revision in the past half century, though both the central and the local authorities have been altered, though research has enlarged our powers of preventing disease, and though a constant increase in public interest has made acceptable a general improvement in health standards. It is gratifying that Sir

KINGSLEY WOOD was able to state on Friday last that, if Mr. WOMERSLEY's Bill were placed upon the statute-book, the Government would produce a further amending Bill, probably in 1926, and would then propose consolidation of the whole law.

Meanwhile Mr. WOMERSLEY's Bill should be regarded as a valuable instalment. Its prospects must not be obstructed. Like every other Bill, it is open to criticism. Those who fear the extravagances of municipal socialism have already noted Clause 61, whereby local authorities which possess slaughter-houses or markets are to be allowed also to possess refrigerators, and to make reasonable charges for cold storage. Critics on the other side will complain that the Bill does not go far enough. Those who care to pick up a modern Local Act and to scan the elaborate clauses which the ingenuity of Parliamentary agents has multiplied, can make a list of the fashionable provisions which Mr. WOMERSLEY's Bill omits to include. He would, for example, allow local authorities to put up drinking fountains, but not to put up seats for the weary. He includes clauses for dealing with disease in common lodging-houses, and clauses against offensive trades, against nuisance from occupation of tents and vans in unsuitable places, and against verminous premises, articles, and persons. He does not include other clauses which are common form in modern local legislation—the power to close Sunday schools in times of epidemics, the power to regulate ice-cream manufacture and sale, the power to make by-laws for better inspection of meat, and the power to prohibit persons from selling food who are suffering from advanced tuberculosis. Criticism on these lines, however, is neither fair nor reasonable. The Bill, neatly as much of it is drafted, will doubtless be improved in Committee; but it is better to obtain a legislative instalment in the form of the greatest common measure of agreement than to lose the Bill by concentrating on points of difference. The general scheme of the Bill is permissive. This fact in itself should disarm hostility.

HIGH MATERNAL MORTALITY: RESOLUTIONS BY THE MIDWIVES' INSTITUTE.

At the last annual general meeting of the Midwives' Institute the following resolutions were passed:—

1. That there should be a post-mortem examination, by a duly appointed pathologist, on every woman who dies in childbirth, unless otherwise disallowed by a competent official. If the post-mortem examination did not reveal the exact cause of death, the coroner should be communicated with and further medical investigation should be made.
2. That the Ministry of Health should be asked for uniformity in the notification of births card, which should have a special place for the name of the person who actually delivers the woman.
3. That the Ministry of Health be asked to request the medical officers of health in their annual reports of puerperal mortality to distinguish between those cases in which a midwife was engaged, and those cases in which a doctor was engaged to attend.

The objects of the three resolutions will commend themselves to our readers. First, the desirability of an autopsy to clear up the pathology of an unexpected, unusual, or sudden event is common to the whole practice of medicine; secondly, infringements of the Midwives Act should be provided against; and, thirdly, any connexion between high mortality and the working of that Act should be made clear. At present the facts demanded by the third resolution can be ascertained only from certain of the annual reports of medical officers of health.

Annotations.

"Ne quid nimis."

THE BATEMAN FUND.

WE publish this week the new subscriptions to the Bateman Fund, and are encouraged to bring the salient points of the appeal before our readers by the following letter which we have received, signed "A. Morse, Staunton-street, Deptford," and "written in the name of Dr. Bateman's patients and friends." Mr. Morse, addressing the Editor of THE LANCET, writes: "We all feel we cannot thank you enough for sending him (Dr. Bateman) back to us so soon. We, the people of Deptford, know what a valuable friend he has always been to the poor. He is called here the poor man's Doctor. We have read and heard how you are subscribing to help Dr. Bateman in his heavy expenses for his trials. God bless you and the medical profession for their loyalty and kindness to him." We have had many letters from members of the medical profession approving our action in opening this Fund, from which we might, with excusable gratification, have extracted sentences for publication, but it is particularly desirable that readers should understand that, in our view, the appeal was *necessary* and not the outcome merely of sympathy in a particular case. This is the reason why the appeal was made. The medical man, and especially the general practitioner, in the course of his business must often find himself in a position of the gravest anxiety, when the procedure that he adopts, his actions, or it may be his inactions, can be placed before a jury of laymen in the wrong light. It is needful, and increasingly needful, that such disasters should be made as rare as possible. The pecuniary risk in such circumstances can be avoided for practitioners by subscription to one of the two excellent Defence Funds, and over and over again we have urged upon our readers to shelter themselves from unavoidable risks. Many of those who have followed the Bateman case must have been led to take this advice, and we bring before them the position of Dr. Bateman as one worthy of their help, if only because his misfortune has stimulated them to obtain security.

INTRATHECAL MEDICATION IN MENINGITIS.

THOUGH the need for drainage and the efficacy of intrathecal medication in certain forms of meningitis are unquestioned, the attempt to administer serum is often abandoned if lumbar puncture is for any reason unsuccessful. Dr. C. Worster-Drought, in the article which appears in our present issue of the series entitled *Modern Technique in Treatment*, points out that even where lumbar puncture fails through the presence of adhesions or through the progressive thickness of the pus, the subarachnoid space may be drained and the appropriate serum administered through other regions. Puncture in the thoracic region is not advisable, since in many normal individuals a posterior subarachnoid space is absent in this region, owing to adhesions between the meninges and the posterior aspect of the spinal cord. But cervical, cisternal, sphenoidal, or ventricular puncture are possible avenues of approach, of which the first, at any rate, has led to successful results in cases of cerebro-spinal fever, reported by several observers, including Cantas and Gerard and Dr. Worster-Drought himself. It is essential to gain access to the subarachnoid space for the application of a specific immune serum, since the full power of the latter can only be exerted when brought into contact with the infecting organisms in a concentrated form. For the actual meningitis, serum injected subcutaneously or intravenously is of little value; not only does it undergo an extremely high dilution in the blood-stream, but there is no evidence that it ever reaches the subarachnoid space. Although the lining membrane of the subarachnoid

space is permeable to substances passing from the cerebro-spinal fluid to the blood, it appears quite impermeable, except in the case of a few drugs (e.g., hexamine), from blood to cerebro-spinal fluid. On the other hand, the absorption of antibodies from the subarachnoid space is fairly rapid, serum injected intrathecally appearing in the blood within 10 minutes¹ and disappearing entirely from the cerebro-spinal fluid within 24 hours.² Dr. Worster-Drought throws doubt on the practical value of hexamine by the mouth in cases of meningitis. It has been given as a routine on theoretical grounds; but though it is certainly one of the few drugs to be even partially excreted by the cerebro-spinal fluid, it must reach the subarachnoid space only in extremely high dilution. Moreover, hexamine dissociates only in an acid medium and the cerebro-spinal fluid is rarely, if ever, acid, even in cases of meningitis. He is probably right in considering the therapeutic action of this drug on the cerebro-spinal fluid as negligible.

THE MIND OF THE MINER.

THE discontent among coal-miners is no post-war affair. The coal trade has been for years in a condition of unrest. Any industrial psychologist who could offer constructive suggestions as to how to make conditions of this work less uncongenial would place the community as a whole deeply in his debt, for in this country the mining industry is more fundamental even than that of agriculture. In an article in last month's *English Review* Mr. James A. Bowie sets out fairly the attitude of owners on the one hand, and miners on the other, and seeks to account for that bellicose mental condition of the worker which appears to be an undeniable factor in the industry. He points out that from 1904-13 the average annual percentage of workers in the coal industry, involved in disputes entailing loss of work, was 21.4; next to these came the textile industry with only 6.4 per cent., while the mean average of all trade groups was 4.4. Since the Armistice matters have been worse; in 1920 and in 1921 national stoppages occurred; in 1922 over one million and a quarter working days were lost due to local disputes, and in 1923 the amount was only slightly less. Yet there has been less unemployment in recent years in this industry than in any other, for in December, 1922, the percentage of unemployed among miners was 4.6, as against 12.2 in all trades, the corresponding figures for 1923 being 2.4 and 10.7. Although coal-mining must for a variety of reasons, such as lack of sunlight, accident risk, and dust and dirt, be an unpleasant occupation, it is not, comparatively speaking, an unhealthy one. The general mortality is not unfavourable, and, according to the Occupational Decennial Supplements issued by the Registrar-General, has been falling steadily, as have also the rates for the chief causes of death among miners. In gold-mining countries silicosis takes a heavy toll, but the Secretary for Mines stated recently in the House of Commons that though the alleged prevalence of silicosis among coal-miners in this country has been under consideration by the Health Advisory Committee for about two years, the evidence so far laid before the Committee is quite insufficient to justify any recommendation in respect of compensation. The fear of silicosis, then, in this country can hardly be a factor conducive to unrest. Moreover, during recent years the accident mortality-rate in mines has continued to fall from 1.6 per 1000 in 1913 to 1.4 in 1918 and to 1.1 in 1923. At the same time, judging from statistics supplied in the House of Commons on Feb. 24th, great mining disasters have been fewer in number and have claimed fewer victims.

Such records must present a difficulty for any medical sociologist who holds that social unrest is an expression of social ill-health. According to Prof.

¹ As shown by Debré with the sensitive precipitin reaction for a foreign serum. (Thèse de Paris, 1911.)

² Hohn, Klin. Jahrbuch, 1909, xx., 377.

E. I. Collis (*Western Mail*, Jan. 21st, 1924), the records within the industry itself show some confirmation of this theory. Mortality records vary widely on the different coal-fields; during over 30 years the comparative mortality-rates for Lancashire and for South Wales have been nearly double those for Nottingham and Derbyshire, and he points out that on all recent occasions, when ballots of the miners have been taken, the greatest unrest has been revealed in Lancashire and South Wales, and the least in Nottingham and Derbyshire. Mr. Bowie suggests that a "dungeon complex," comparable to the "prison complex" of the factory hand, is present in the subconscious mind of those who toil in darkness amid dirt and dust. Support for such a line of argument comes from the existence among coal-miners of a disease peculiar to them—nystagmus; a disease which, while it prevails directly as illumination in pits diminishes, is recognised to possess a pronounced neurasthenic basis. As coal-mines are steadily being deepened, danger from mine gases increases; hence the use of safety lamps, which give less illumination than naked lights, has been rapidly on the increase. Thus in 1907 there were about 600,000 safety lamps in use, while in 1923 there were over 900,000. The solution of problems existent in the miner's psychology may possibly be found closely associated with the *raison d'être* of miners' nystagmus. This thought is worth pursuit, for provision of better illumination in our coal-mines would seem to be a simpler expedient than many of the economic and administrative proposals which to-day are vaunted.

INFECTIOUS DISEASES IN SCHOOLS.

THE closure of any school on grounds of infectious disease is usually resented by parents, since the responsibility for watchful care and possibly for isolation is thrust on them. Their resentment is increased if they believe economic considerations to be a factor in the decision to close down. Headmasters of private preparatory schools who are tempted to spare themselves anxiety by packing off the children even a few days before the end of any term know well that they will not escape abuse unless the step is taken on the urgent representation of the medical officer in charge. It is the latter, therefore, who is usually made responsible for a decision and should prepare himself by mastering the complicated issues involved. An attempt to obtain guidance by studying the procedure adopted in schools not run for profit shows him that here financial considerations have been an important factor in the decision, since grants from the Board of Education depend on the maintenance of good average attendances throughout the term. To run the school with a bad attendance sheet for any reason is to run it at serious economic disadvantage. New regulations, however, have just been issued whereby local authorities will, in future, be secured from loss, if the low attendance is due to the prevalence of infectious disease, and closure of primary schools will only be allowed strictly on medical grounds. These regulations are set out in a memorandum¹ addressed to medical officers of health and school medical officers. Published under the joint auspices of the Ministry of Health and the Board of Education, the memorandum includes a theoretical discussion of the principles involved as well as specific rules for action in particular diseases, and will doubtless be welcomed by medical officers attached to every type of school. It is a new edition of a pamphlet first issued in 1909, and reaffirms the principle, then laid down, that if, during epidemics of infectious disease, the power to exclude individual children from school be used to the best advantage, it is only in special and quite exceptional circumstances that it will be necessary to close a school in the interests of public health. There will, indeed, be no temptation in the future for local education authori-

ties to close down on any other grounds, since security against loss of grant is assured to secondary as well as primary schools.

The mode of procedure recommended is carefully set out in the memorandum, and the medical officer of health is advised in certain cases to act, not as such, but as school medical officer, since he has greater powers in the last-named capacity. Incidentally, it is again urged that these two offices should be held by the same person. The general effect of the new regulations is as follows: (a) Schools or departments may be closed or individual scholars excluded by the Sanitary Authority or by any two members thereof acting on the advice of the medical officer of health. (b) Schools or departments may be closed for medical reasons by the Local Education Authority acting on its own initiative—i.e., without orders from the Sanitary Authority—but the closure must be advised or approved by the school medical officer on the ground that such closure is needed for medical reasons. (c) Individual children may be excluded from school by the school medical officer (without special authorisation by the Local Education Authority in each individual case) provided that the Board are satisfied that proper arrangements have been made by the Local Education Authority for this purpose. Generally speaking, the advice given in that part of the memorandum which deals with specific diseases is admirably complete. The omission from the discussion of diphtheria of any reference to the Schick test will disappoint those who will look for a critical estimate of its value in these pages. The recommendation that cases of influenza should not be readmitted until a careful examination of the heart and lungs has been made to eliminate possible latent complications is a counsel of perfection. There can hardly be a school medical officer who would put such a proposition before his Authority during an epidemic, considering what the risks amount to and what the cost would be. The remarks under the heading *Acute Poliomyelitis* should receive strict attention. It is emphasised that a careful watch should be maintained in non-paralytic cases for the supervention of paralysis, as recurrent cases occur in which the paralysis is manifested after acute symptoms have subsided. Paralytic cases require a long period of school exclusion and are afterwards better treated, if practicable, in special orthopaedic institutions. In such cases early care and educational measures maintained over a prolonged period may prevent or at least mitigate crippling. Recommendations for the care and after-care of children suffering from encephalitis lethargica conclude the memorandum. Children exhibiting signs or symptoms suggestive of a mild or abortive form of encephalitis lethargica should, it is said, be kept from school for a minimum of six weeks. Six months from the time of exclusion from school is suggested as the earliest period at which a child who has had encephalitis lethargica may return to work; in many cases this period has to be extended to a year or longer. So little is known about the epidemiology of this disease that more concrete advice is not to be expected.

THE VISIT OF FOREIGN PUBLIC HEALTH OFFICERS.

THIRTEEN nations have during the last few weeks been represented by their foreign public health officers in an official visit to this country under the auspices of the League of Nations.¹ The representatives visited certain typical selected centres, such as Leeds and a Yorkshire district, the borough of Wolverhampton, a large suburban borough, and various areas in the counties of Middlesex and London, and under the auspices of the local officials were given full information as to national and municipal public health organisation. The visit concluded at the beginning of this week, when the representatives left for Geneva, there to present a report to the League.

¹ Memorandum on Closure and Exclusion from School. H.M. Stationery Office. 1925. Pp. 32. 4d.

² THE LANCET, Feb. 14th, 1925, p. 354.

and its termination was marked by a luncheon given to them by the Government, over which Sir John Gilmour, Secretary of State for Scotland, presided. The luncheon was not allowed to offer opportunity for many or long speeches, but in proposing the health of the visitors Sir John Gilmour struck a note that was acceptable to the company and would be received with acclamation by any thinking audience, when he said that all persons of intelligence were looking anxiously to a peaceful settlement of the world, and that preventive medicine furnished a means for mutual development and intercomprehension between all nations. Dr. M. D. Horst, the representative of Holland, replied for the visitors, and while acknowledging the pioneer part played by Great Britain in health organisation and extolling the extent to which multiple activities were ranged under the common title of Health Department, raised laughter by saying that this country appeared to pay no special regard to the value of vaccination. The company, however, warmly applauded his further remarks founded on personal observation of the value of vaccination. The luncheon took place at the Carlton Hotel, London, W.

THE SEASONAL PREVALENCE OF DISEASE.

PERIODICITY is one of the interesting phenomena in epidemiology, and a study of the causes of cyclic tendencies of disease discloses fundamental factors of importance. To be able to elucidate the laws which govern these periodic eruptions is to be able to presage their advent and to formulate measures for preparedness and prevention, and to this subject Dr. M. J. Rosenau made a valuable contribution in a paper read at the International Conference on Health Problems in Tropical America.¹ Pandemics of influenza have been quite irregularly spaced. Measles, again, is a disease which tends to recur in a cyclical manner with considerable regularity. In the endemic regions exacerbations recur every two or three years. The explanation appears to depend upon the accumulation of a new crop of susceptible children. Infantile paralysis in Massachusetts displays a sort of regularity in its tendency to an excessive prevalence about every fourth season. These epidemic recurrences are followed by a regular decline until the next period. Despite the vagaries and uncertainties of this disease, we do know that, as long as the disease prevails, there will be more of it in the summer-time than in the cold season.

A good instance of the uncertain manner in which epidemic diseases recur is shown by the visitations of plague in London from 1563 to 1680. Consequently, plague is one of the diseases which have become stamped upon art, science, and literature. Plague was raging in Stratford-on-Avon when Shakespeare was a baby. Another example of irregular periodicity is shown by the story of diphtheria epidemics in Boston, New York, and Chicago, but within recent years such epidemic outbreaks have not taken place and the disease should never again be allowed to get out of hand. Many diseases recur annually with the regularity of perennials. However, seasonal prevalence of disease may to a certain extent be violated when a communicable infection is introduced into a virgin population. But on the other hand, when certain contact diseases which prevail especially in the winter season in temperate latitudes are introduced into the tropics, they have a tendency to die out; thus scarlet fever has never gained a foothold in tropical countries, and measles and diphtheria do not, as a rule, become serious problems under the vertical rays of the sun. Yet influenza, pneumonia, and tuberculosis play havoc in tropical lands just as they do in temperate zones. The effect of latitude is striking and significant; thus rheumatic fever reaches its highest incidence in March and April in the United States, but in September and October in

England. A number of diseases show two peaks of incidence, one in the spring, the other in the autumn. This is frequently the case with the acute respiratory and throat infections, but also with tuberculosis, nephritis, and rheumatism. The causes of seasonal changes in health and disease are varied, complex, and largely undetermined. The insect-borne group of diseases prevail almost entirely during the summer-time—that is, during the hot, moist season of the year when the insect vectors most abound. These insect-borne diseases give us the best examples in epidemiology of endemicity. We have, therefore, no record of an epidemic of yellow fever in the winter season.

An exception to the rule is typhus fever, which prevails in winter-time, but subsides with the warm weather. This paradox is, however, easily explained by the fact that lice are more common in cold weather. There is evidently some factor in the bionomics of the louse which makes cold weather favourable for the completion of the cycle of events. Malaria may, however, occasionally be more prevalent in winter than in summer. An instance of this has recently been reported from Russia in the winter of 1922-23, where an epidemic spread steadily throughout the winter with the thermometer varying from 20° to 30° C. below zero, the spread of the disease being apparently due to the fact that the butts of drinking-water in the almost tropical heat of the log houses of the peasants afforded ideal breeding-places for the anopheles. The seasonal prevalence of the intestinal diseases has a general resemblance to that of the insect-borne infections. This is the case with typhoid fever, cholera, dysentery, and the summer diarrhoea of infants. The incidence and intensity of these infections become greater as we approach the tropics. Winter-borne outbreaks of intestinal infections frequently occur. Water-borne typhoid fever has a predilection for the winter season. When cities like Albany, Philadelphia, and Chicago improved their water-supplies the typhoid fever rate became markedly lower and the seasonal prevalence was reversed.

The importance of the seasonal prevalence of disease is further emphasised by the fact that such diseases as poliomyelitis and encephalitis lethargica, which in Britain have their period of maximum incidence in the late summer and autumn and in the winter respectively, occur under reversed conditions in Australia, where poliomyelitis is a disease of the first half of the year, and encephalitis of the third and fourth quarters. This point was mentioned by Dr. A. K. Chalmers, medical officer of health for Glasgow, in the course of the Watsonian lectures delivered recently to the Royal Faculty of Physicians and Surgeons of Glasgow.

THE CARE OF CRIPPLED CHILDREN.

THE County Borough of Portsmouth has found a happy solution of the problem of how to deal with the crippled children in its district. At a meeting in Portsmouth Town Hall on March 20th the Mayor, Councillor F. Privett, was enabled to hand over to the trustees of the Lord Mayor Treloar Hospital for Cripples, Alton, a cheque for £10,000, raised by voluntary subscription, in return for which the trustees have agreed to set aside 50 beds in perpetuity for the treatment of the young cripples of Portsmouth. It is little over a year ago that certain citizens of the borough decided to raise a fund in order to provide treatment for the town's crippled children. The first idea was to erect a small orthopaedic hospital on the outskirts of the town; further consideration, however, showed that the money could be more advantageously expended by endowing beds in an existing institution. As a result of this decision the trustees of the Hospital at Alton were approached and agreement was arrived at. By a trust deed the Portsmouth Corporation have now allotted to them 50 beds for which they pay a maintenance charge of 30s. a week. The

¹ International Conference on Health Problems in Tropical America, United Fruit Company, 1924, pp. 28-54.

surgical staff of the Hospital, whose original efforts took cognisance mainly of crippling caused by tuberculosis, has been extended to cope with different forms of orthopaedic work, and the crippled children of Portsmouth up to the age of 16 years, no matter to what cause the infirmity may be due, can now secure at Alton whatever treatment, surgical or otherwise, may be necessary. The agreement has received the cordial approval of the Ministry of Health and Board of Education, and the procedure adopted by Portsmouth is one which, provided the trustees of the Treloar Hospital were agreeable, might well be followed by local authorities in the locality. Other counties might well consider the advantage of similar centres in their midst, and make the development possible by financial support. Education authorities must shortly make provision for the crippled children of their districts, and to attempt to do this by the erection of small *ad hoc* hospitals will not only prove expensive but, what is still more important, such a course can never secure for their patients the efficient treatment which is available at a large institution capable of engaging a highly specialised surgical and medical staff.

OXALURIA.

Calcium oxalate is a normal constituent of the urine, but in conditions of health the amount is small, between 15 and 20 mg. being excreted during 24 hours. Upwards of 30 mg. may be considered as pathological, though this quantity may not cause any definite symptoms. Its solubility in the urine is small and varies with the reaction, for in very acid urine probably the normal quantity present is completely dissolved; but in amphoteric, alkaline or even slightly acid urines only a minute trace goes into solution, the remainder being passed as crystals. Oxalic acid is produced from a large number of substances in the human body—for example, from the carbohydrates by oxidation, from protein and nucleo-protein by breaking down of their complicated structure, and even from fats and allied substances such as glycol. In addition, oxalic acid and its salts are present in varying proportions in many common foodstuffs, amongst which the following are examples—spinach, rhubarb, sorrel, gooseberries, strawberries, beetroot, cocoa, tea, and chocolate. Briefly, the sources of oxalic acid formation in the human body during the processes of digestion are very numerous. There is one additional fact of physiological importance—viz., the relatively greater solubility of magnesium oxalate than the calcium salt, for the suitable administration of magnesium salts in the diet can increase the amount of oxalate excreted, and so diminish the tendency to oxaluria.

The surgical manifestations of oxaluria are not realised, and Mr. Bathe Rawling was able to collect an interesting array of facts and warnings in his paper to the Medical Society of London on Monday evening. He dealt first with that group of cases in which the oxaluria produces an abdominal condition, which may be, and has been, diagnosed as acute intestinal obstruction. Mr. Rawling's first patient, manifesting this condition, was his own house surgeon, who was suddenly seized with abdominal pain accompanied by vomiting, abdominal distension, and complete constipation. The patient was seen by Sir D'Arcy Power and Sir Anthony Bowlby as well as by Mr. Rawling. All agreed that acute intestinal obstruction was present and a laparotomy was performed with a negative result. The next day, the patient having shown no improvement, a general surgical consultation revealed a unanimous opinion that acute obstruction was still present, and a second exploration was advised. Fortunately the patient passed small quantities of flatus, and enemata now succeeded in producing admirable results, a second operation becoming unnecessary. The urine was later found to be smoky with blood and heavily laden with oxalate crystals,

and later a small calculus was passed. Quite soon after Mr. Rawling saw a second example, again in a medical man, who presented a very similar clinical picture, but the condition was diagnosed without operation. The noticeable feature in both cases was that the patients neither felt nor looked as ill as they should have done if their trouble had really been acute intestinal obstruction. Furthermore, in the first case the patient was convinced that the paralytic condition of the intestine was largely due to a dose of morphia. These cases Mr. Rawling cited as examples of acute abdominal manifestations accompanying oxaluria, but there are other and more numerous examples of chronic intestinal disturbances due to the same cause. They may be somewhat vividly described as "windy" patients, who suffer from recurrent attacks of abdominal pain with distension, neither very severe but of sufficient intensity to make the patient seek advice. The explanation suggested by Mr. Rawling is that there is a reflex disturbance of the sympathetic nervous system controlling the intestines from the renal nerves. The existence of such abdominal manifestations calls attention to the great importance of a routine examination of the urine, and further it must be realised that the general condition of these patients is not consistent with the diagnosis of acute intestinal obstruction. Apart from the well-recognised group of patients who suffer from hæmaturia due to oxaluria, there is one other surgical condition found at times complicating an excess of oxalates in the urine, and that is a urethral discharge, which may vary from a slight mucous stickiness to a frank muco-purulent discharge. The importance of this class of case cannot be overestimated, for the obvious mistake in diagnosing gonorrhœa may have disastrous effects to both patient and surgeon. Sir William Willcox, in the course of the same debate, dealt with the physiological source of the oxalates and the treatment of their excess in the urine, and in doing so afforded a well-timed warning that the presence of calcium oxalate crystals does not necessarily entail oxaluria, and that such grave conditions as had been mentioned can only be attributed to oxaluria in the absence of definite evidence suggesting other more obvious lesions. He recommended careful dieting by excluding all those foodstuffs known to be rich in oxalates, by choosing foods rich in magnesium, by avoidance of hard drinking waters, and the establishment of a proper hygienic habit of life.

A SOCIAL evening will be held by the Royal Society of Medicine at 1, Wimpole-street, London, W., on Monday, May 4th, when Dr. Robert Hutchison will give an address on "Dr. Samuel Johnson and Medicine," illustrated with 18th century portraits.

THE announcement was made last week, as these pages were in the press, that Sir Humphry Rolleston, in accordance with universal expectation, has been appointed to follow his old friend Sir Clifford Allbutt as Regius Professor of Physic in the University of Cambridge. On every ground the appointment has been hailed with satisfaction.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The twenty-second meeting of the Commission was held at the Home Office, Whitehall, on March 19th, Sir Andrew Duncan in the chair. The examination of Sir Norman Hill, Bart., on the working of the Seamen's National Insurance Society was resumed and at its conclusion he gave evidence as to the special fund for seamen. Thereafter the Insurance Committees of Coventry (Mr. H. W. Wale and Mr. Lee Gordon), Cheshire (Mr. G. Wright and Mr. F. T. West), and Leicestershire (Alderman Goodacre and Mr. T. Crew) gave evidence on the constitution and administrative work of insurance committees, particularly with reference to the medical and treatment benefits. The Commission announce that proof copies of the oral evidence and the relative statements submitted at the meeting of March 5th are now on sale at H.M. Stationery Office (2s. 3d.).

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXV.—THE TREATMENT OF MENINGITIS.

THE prognosis in acute and subacute leptomeningitis varies according to the organism responsible for the infection. Cerebro-spinal fever (meningococcal meningitis) is by far the most hopeful as regards response to treatment, but many cases of recovery have now been reported in the pneumococcal, streptococcal (especially of otitic origin), and influenzal (*B. Pfeiffer*) forms of meningitis, as well as in that due to various other organisms. Even in tuberculous meningitis, which has the worst possible prognosis, some 46 authentic cases of recovery are recorded in the literature.

General Management.—Careful nursing is of paramount importance. The patient's head should be kept fairly low, not more than one pillow being allowed; sitting up is not permitted. Unconscious patients must be turned frequently, since hypostasis is a predisposing factor in the development of pneumonia. In cases running a course of longer than ten days a water-bed should be provided to obviate bed-sores. The patient must not be allowed to suffer from retention of urine; if necessary, the catheter must be used twice daily.

Diet.—In acute cases, milk, beef-essences, cocoa, and lemonade are given. If vomiting is present, four-hourly feeds consisting of 5-15 oz. of citrated milk (sod. cit. to gr. 2 per oz. of milk) diluted with an equal part of water are often kept down. Peptonised milk whey, and albumin water are also useful. In cases recovering, semi-solids—custards, bread-and-milk, eggs, under-done mutton—should be given as early as possible. Infants suffering from posterior basic meningitis should be breast-fed if possible.

Bowels.—Constipation is the general rule. Calomel or castor oil may be given at night, followed by a saline purge next morning. Liquid extract of cascara and compound liquorice powder are also useful, but enemata are frequently required.

Vomiting.—To allay mild vomiting not due to hydrocephalus, the following mixture is often helpful: R Acid hydrocyanic dil. M4, liq. morphinae hydrochlor. M10, sodii bicarb. gr. 10, aq. chloroformi ad 3 i., t.d.s. The most efficacious measure for the prevention of vomiting, however, is repeated daily lumbar puncture (vide infra).

Headache.—Cold applications are beneficial. Phenacetin (gr. 12) with caffeine (gr. 2) may be given twice or three times daily.

Sleep, &c.—Sulphonal (gr. 20-30) is often useful. For obstinate insomnia, or when continued delirium with restlessness is present, morphine (gr. ½) should be administered hypodermically and repeated if necessary. When morphia fails, potassium bromide (gr. 15-25) sometimes gives good results. Paraldehyde is of little value in meningitis, and hyoscine should be avoided. Warm sponging and occasional warm packs are also of help.

Should symptoms of cardiac failure or a falling blood pressure develop, hot saline infusions (T. = 100° F.) should be given rectally or subcutaneously in the pectoral regions, together with digitalin (gr. 1/100). Strychnine, owing to its tendency to precipitate convulsions, is contra-indicated. Cases recovering should remain in bed at least 14 days after the termination of the course of disease. Patients recovering from cerebro-spinal fever should sniff a solution of 1 per cent. chloramine into the nose twice daily in order to sterilise the naso-pharynx; relapses may be due to a reabsorption of meningococci from this situation.

Special Treatment.

Two principles are important. (1) The establishment of adequate drainage for the meningeal exudate;

(2) the application of a specific immune serum in as close contact as possible with the inflamed tissues.

Drainage.—Adequate drainage can usually be supplied by the performance of repeated daily lumbar puncture. Since 1916, more especially in cerebro-spinal fever, my routine practice has been to follow a period of intrathecal serum administration by repeated daily lumbar puncture, with complete drainage of the subarachnoid space, until the cerebro-spinal fluid becomes clear to the naked eye. With this method I have encountered no recrudescence nor relapses. When no cerebro-spinal fluid is obtained by lumbar puncture ("dry-tap") by reason of adhesions existing between the meninges and spinal cord at a higher level or a progressive increase in the density of the pus, one has to consider puncture at other sites.

Cervical Puncture.—Puncture of the theca below the seventh cervical vertebrae I have found quite a safe procedure provided the needle is inserted without a stylet.¹ Puncture in the thoracic region is not advisable, as in many normal individuals a posterior subarachnoid space is absent in this region.

Puncture of the Cisterna Magna.—The technique of cisterna puncture is as follows: With the patient prone and his forehead supported, the needle (graduated in centimetres) is inserted directly over the spine of the second cervical vertebra, the point being directed upwards in the mid-line at an angle of 45°. The needle pierces the occipito-atlantal membrane between the occipital bone and atlas, and reaches the cisterna magna at a depth of 4 to 6 cm. This method of puncture is indicated when no fluid can be drained off at any lower level. Occasionally, when purulent exudate occludes the region of the foramen magnum, even this puncture may fail in its object.

Sphenoidal Puncture.—If the above measures are unsuccessful, sphenoidal puncture—after the method of Bériel and Cazamian—may be tried. This consists of introducing a needle 2 mm. external to the supra-orbital notch, upwards and inwards along the outer wall of the orbit in its upper part, and entering the most external portion of the sphenoidal fissure.

Ventricular Puncture.—In children with open fontanelles, puncture of the lateral ventricle is easy and may be resorted to at once if lumbar puncture fails to yield fluid. The needle is introduced at the lateral angle of the superior fontanelle, the direction being downwards, slightly backwards and inwards to a depth of 3 cm. In older children and adults, the usual method of draining the lateral ventricles is to trephine, a procedure which causes considerable "shock," especially as it is necessary to operate on each side. The patient seldom survives, and this operation should not be considered unless the patient's condition is almost desperate.

More recently, instead of trephining, I have merely drilled a hole through the skull over Keen's point and punctured the ventricle through the small opening thus made. In most cases it is possible to perform this operation without an anaesthetic, the "shock" is negligible as compared with that resulting from a trephine, and drainage appears equally effective. Two cases of apparent internal hydrocephalus complicating meningococcal meningitis treated by this method recovered.

As regards meningitis secondary to otitis media or other local infection, an attempt should be made to remove the original septic focus and to establish free drainage of the subarachnoid space. In otitic meningitis the translabyrinthine method of drainage has resulted in several recoveries.

Administration of Serum.

In order to exert its maximum effect, serum must be introduced directly into the subarachnoid space and must be renewed at intervals not exceeding 24 hours. When there is evidence of systematic infection, the intrathecal medication should be

¹ Jour. Neurol. and Psychopathol., 1921, i., 216.

supplemented by the intravenous administration of serum in doses up to 200 c.cm. Herrick, indeed, advises doses up to 600 c.cm., the resulting serum-sickness being no more severe than with smaller amounts. Anti-meningococcal, anti-pneumococcal and anti-streptococcal sera are available for the respective forms of meningitis. Also, for the very rare cases of meningitis due to *B. typhosus* and *B. dysenteriae*, we have anti-typhoid and anti-dysenteric sera. The serum should be polyvalent for the specific organism obtained from the cerebro-spinal fluid and is administered at the earliest possible moment. Later, if the actual type of organism is determined in the case of the meningococcus or pneumococcus, the corresponding univalent serum can be substituted.

Method of Administration.—The usual method of introducing serum into the subarachnoid space is by puncture in the lumbar region, from which situation it quickly reaches the ventricles.

Following the evacuation of cerebro-spinal fluid in any region, the serum is injected either with a syringe or run in from a small funnel and tube—the last-named method being safer. The end of the bed should be raised for half an hour following the serum administration. For the performance of lumbar puncture and intrathecal injection, a general anaesthetic is only necessary when the patient is particularly restless or violent. In restless cases a hypodermic injection of morphine (gr. $\frac{1}{4}$) and atropine (gr. 1/100) given 20 minutes before the puncture will assist in keeping the patient calm.

Dosage of Serum.—The initial dose of serum is from 30–50 c.cm., followed by 30 c.cm. daily for at least four days or until clinical improvement is manifest. The quantity of serum injected should, however, be at least 5 c.cm. less than that of the cerebro-spinal fluid withdrawn. To children the following doses may be given: 1–5 years, 5–15 c.cm.; 5–10 years, 10–20 c.cm.; 10–19 years, 20–40 c.cm. However great the patient's improvement may appear, serum injections should be continued until no more organisms are present in stained films of the cerebro-spinal fluid deposit. After this period repeated daily lumbar puncture is advisable until the cerebro-spinal fluid is clear to the naked eye. At each puncture the fluid is allowed to escape until the flow practically ceases. Should signs of a recrudescence appear the injection of serum must be resumed; if the period since the last serum administration exceeds eight days anti-anaphylaxis must first be induced.

Other Methods of Treatment.

As regards other forms of meningitis for which no specific sera are available, it is best to rely on general treatment and the performance of repeated daily lumbar puncture. In very acute cases puncture may be performed at first every 12 hours. The introduction of chemical substances—lysol, protargol, flavine, hexamine, &c.—directly into the subarachnoid space is not to be recommended, nor have I observed any benefit result from attempts to wash out the intrathecal space with saline solution.

It is usual to prescribe hexamine (gr. 10, t.d.s.) by the mouth in all cases of meningitis. It is, however, of doubtful value. Recently Maloens² has advocated the intravenous injection of an iodo-urotropine preparation in septic meningitis, each injection being preceded by lumbar puncture. Vaccines are applicable only to subacute and chronic cases, and cerebro-spinal fever and tuberculous meningitis are the only two forms which exhibit such stages with any degree of frequency. In the former, an autogenous vaccine may be given, starting with a dose of 200 million organisms and increasing by 200 or 250 millions per dose every fifth day up to a maximum of 2000 millions. The reactions with these doses are negligible.

THE ACTION OF WATER UPON COPPER PIPES.

BY JOHN C. THRESH, M.D. MANCH., D.Sc. LOND.,
F.I.C., &c.

COPPER pipes have apparently been used on a limited scale for many years as service pipes for conveying water; tinned copper pipes and cylinders are very largely used for hot water installations, and in many cases this hot water is laid on to the kitchen and the water is used for domestic purposes. Apparently in some cases plain copper pipes and cylinders are used, in which case the water would be in immediate contact with the metal.

Recently one of these installations was examined, and the water as supplied to the institution was found to contain 0.04 parts of copper per 100,000. The whole plant had been in use for years, and the hot water was used for all purposes without giving rise to any complaints or even to any suspicion of its being unwholesome. The question submitted to me by the architect was, whether I could approve of a similar installation for a much larger institution in the same district using water from the same public supply, which water had a marked effect upon iron and galvanised iron pipes, especially when hot. Before expressing a definite opinion I put myself in communication with people using copper pipes and with the "Copper and Brass Users Association." At their request a series of experiments were also undertaken (the results of which will be referred to later), and finally I expressed the opinion that copper pipes could be used for the institution with perfect safety.

Effect of Ingestion of Minute Quantities of Copper.

Meantime careful research was made for records of the action of copper on the human body, and it was only in out-of-date publications that the opinion was expressed that cases of chronic copper poisoning did occur from the ingestion of minute quantities of copper, and in these cases they never appeared to arise from the use of copper pipes for water or copper vessels for cooking. Until a comparatively recent period, however, there seems to have been a widely held opinion that copper was as poisonous as lead, but this opinion began to be doubted when the causes of food poisoning were investigated. Before this period, if any article of food or drink had caused illness, and had been in contact with copper, no further investigation was deemed necessary. The poisoning was attributed to the copper. Within the last five years a jury returned a verdict of "death from copper and lead poisoning" because the analyst who examined the stomach certified that he found traces of lead and copper therein. The water used in the neighbourhood was said to act on lead, but chronic lead poisoning was unknown, and when the water was, at a little later date, carefully examined it was found to have a barely perceptible action on lead. The symptoms as described by the parents indicated that death was due to food poisoning. The trace of lead found in the system may have been derived from the water; copper is a normal constituent of the body. Cases of this kind get recorded and the erroneous nature of the conclusion may be difficult to prove. In connexion with copper poisoning, if cases of this kind are excluded, there is no evidence of copper in small quantities being a poison or of its being able to produce a condition of chronic poisoning. Of all the authorities consulted two only need be quoted.

Prof. W. E. Dixon, F.R.S., in his "Manual of Pharmacology" (4th edition, p. 412), says:—

"There is no evidence that man is ever affected with chronic copper poisoning, so that the use of copper cooking

vessels and the employment of minute amounts of copper to 'improve' the appearance of peas, may not be so harmful as might be supposed."

Dr. Dixon Mann, in his "Forensic Medicine and Toxicology," 2nd edition, p. 484, refers to the older views about copper poisoning and adds:—

"Formerly toxicologists shared these views and never questioned the existence of chronic copper poisoning; modern authorities, on the other hand, with few exceptions, state that it is unknown . . . For the present, whilst allowing the possible existence of chronic copper poisoning, it may be accepted that the cumulative action of minute doses of copper is infinitely less injurious to human beings than is the case with similar doses of lead . . . Copper is almost constantly present in the system and is chiefly eliminated by the bowels."

It is now well known that wheat, barley, and many other articles of food and drink contain copper, hence the presence of traces in the human body.

The Limits of Safety.

Lehman (Archiv Hygiene, xxiv.) calculates that each individual takes into his body daily 20 mg. of copper, and Tschirch, confirming this, adds that so long as the total quantity of copper ingested does not exceed 100 mg. daily there can be no question of injury to health. In works on practical hygiene or water analyses, whilst details for the method of detection are given, an opinion is rarely expressed as to the amount permissible. Wanklyn deals with lead and copper as though their effects were identical, and simply says: "Water should contain less than 1/10 of a grain of lead or copper per gallon." Lehman, in his "Methods of Practical Hygiene," translated by the late Sir William Crookes, appears to regard copper as practically harmless, saying: "The danger of chronic poisoning by . . . or drinking water . . . probably never existed." From a careful consideration of all the evidence available I have arrived at the conclusion that when the average amount of copper in the whole day's supply does not exceed 1/10 gr. per gallon (= 0.14 parts per 100,000) the water can be considered as perfectly wholesome.

Action of Potable Waters on Copper and Tinned Copper.

Having arrived at this conclusion it became necessary to ascertain the action of potable water on copper and tinned copper, and, as these articles may vary considerably, certified specimens were obtained of (a) electrolytic copper, (b) copper complying with the specification of the British Engineering Standards Association, which contains 99.25 per cent. of the pure metal, and (c) the G.P. standard copper, which contains 99.7 per cent. of pure metal. It may be said at once that no appreciable difference in the action upon any of these three could be detected whatever the nature of the water used in the experiment. Two kinds of tinned copper were obtained, one in which the coating contained 99 per cent. of pure tin, and the other in which the coating only contained 50 per cent. of tin. The remainder was obviously lead, and whilst the copper coated with 99 per cent. tin practically withstands the action of all, except acid, waters, the 50 per cent. tin coating yields lead almost as freely as an ordinary lead pipe. Copper coated with 99 per cent. tin may be generally applicable, but the copper coated with 50 per cent. tin is as dangerous as lead, and its use for water service pipes should be strictly forbidden. If the water is one which does not act on lead, then the tinning is unnecessary, and only adds to the cost of the pipes. If the water acts on lead, then there is no advantage in using this so-called tinned pipe and it becomes a great source of danger, since the user, deeming himself safe in using tinned copper pipes, is running all the risks of lead poisoning exactly as though he were using lead pipes. One of the acid waters experimented with took up a dangerous amount of lead from a copper pipe coated with the 99 per cent. tin, but waters of this type are very exceptional.

New copper pipe is a little more freely acted upon for the first few days. This is probably due to the

rough surface and a thin coating of oxide. The effect of surface is shown if three copper slips of the same size are put into equal volumes of the same water and allowed to stand for an equal number of hours. A strip which has been exposed to air, used in this condition, yields more copper than a strip which has been cleansed by rubbing with petrol and finest emery, whilst a strip which has been burnished by more vigorous treatment in the same way will yield much less metal to the water than either of the others. If the water is changed daily from the third or fourth day the results obtained are practically identical, showing that the effect of surface has passed away.

The action of water on copper is similar to that of the action on lead, the metal taking up oxygen from solution and an oxide being formed. The solubility of the copper oxide is very much less than that of lead oxide, and the affinity of the copper for oxygen appears to be very much less than that of lead. Possibly about 0.025 part per 100,000 copper or oxide may be in molecular solution, but anything above this seems to be in a colloid condition or in a state of coarse suspension, since filtration through fine filter-paper, asbestos, or porcelain removes nearly all the copper. When any appreciable action is taking place the water becomes dull, but under ordinary circumstances (unlike lead) no visible deposit forms; therefore there does not appear to be any danger from deposits in the pipes.

Cautions in the Use of Copper Pipes.

Under certain conditions, as when an electric current traverses the pipes, action is enormously accelerated and a perceptible pale-blue deposit forms which easily dissolves in very dilute acid and gives a blue colour when an excess of ammonia is added. It is obvious, therefore, that such pipes should not be used for earthing currents. It may be added that in recent years complaints of the action of water on metal pipes have greatly increased in frequency, and there is little doubt that the cause is the use of such pipes, especially by amateur electricians, for this purpose.

When copper pipes are now in use the only complaints which occur are (1) of a green deposit at joints, and (2) the green staining of porcelain enamel by drippings from taps. These effects are due to the accumulation of copper oxycarbonate from the evaporation of the water, and are easily remedied if proper attention is given to the joints and taps. They do not necessarily indicate a dangerous condition of the water.

Experiments with Various Waters.

Experiments have been made with waters derived from large sources of supply from all parts of the kingdom, and waterworks engineers, analysts, and medical officers of health have shown their interest by collecting and sending typical samples.

With water of different types the following results were obtained:—

	Copper.*		Copper.*
River water of moderate temporary hardness—		Moorland water (cont.)	
London	0.04	Hardness 1° ..	0.057
Surrey	0.025	" 1° ..	to 0.075
Hampshire ..	0.035	" 2.75° ..	0.15
An unfiltered river water	0.06	" 1° (very acid) ..	0.65
Deep well waters—		Acid neutralised with chalk ..	0.01
Chalk	0.000	Hardness 2.3° ..	0.05
Limestone ..	0.05	" 4° ..	0.00
New Red Sandstone	0.01	" 0.5° ..	0.10
An alkaline water—		" 4° ..	0.045
Thanet Sand ..	0.04	" 5° ..	0.06
Ditto	0.025	Spring waters—	
Greensand water—		Hardness 21° ..	0.05
Hardness 4° ..	0.01	" 3° ..	0.075
Moorland water—		" 15° ..	0.06
Hardness 4° ..	0.033	Very pure distilled water—	
" 3° ..	to 0.065	Hardness 0° ..	0.14-0.20
" ..	0.01	+ 4 mg. MgCl ₂ , hardness 4° ..	0.020
		+ 4 mg. NaCl, hardness 0° ..	0.01

* Copper taken up in 24 hours (parts per 100,000).

The process for estimating the copper which gives the most reliable results is exactly the same as that for estimating the action of water on lead, described in "The Examination of Waters and Water Supplies"¹ (third edition, p. 332), copper foil being substituted for lead foil, and a solution of copper sulphate for the standard lead acetate.

Comparative Solvent Powers of Hot and Cold Water.

Experiments were made with hot water and the results indicate that so long as the water contains oxygen and remains in contact with copper some metal is taken up, for example—

A neutral water—	
Copper taken up by cold water in 24 hours..	0.005 and 0.01
Copper taken up by nearly boiling water in 48 hours	0.033 „ 0.065
An acid moorland water—	
Copper taken up by cold water in 24 hours..	0.065
Copper taken up by nearly boiling water in 48 hours	1.3
Repeated	1.44

In cold water the amount of copper taken up in three hours is one-third to one-fourth of that taken up in 24 hours. When the action is very slight in 24 hours, the amount of metal taken up in three hours is too small to estimate, though its presence can be detected by the reduced phenolphthalein test, which will show one part of copper in 100 million parts of water.

Whatever the nature of the service pipes used, the water which has stood therein throughout the night should be run off before any is drawn for drinking or beverage-making purposes. It is exceedingly likely that if this precaution were always taken there would be fewer complaints of turbidity, and the risk of any effect upon health would be largely decreased. It is especially necessary where lead pipes are used, and it will be advisable where copper or galvanised iron is utilised.

That very minute quantities of copper in water have an algicidal and bactericidal action is well known, but water standing in copper pipes for 24 hours cannot be depended upon to be free from objectionable bacteria. Very conflicting results have been obtained, yet the above statement seems well established.

Arsenic in Copper.

It is well known that arsenic, in traces, is found in most copper, and experiments were made to ascertain if any was taken up by water. Only one sample of water was found to take up any trace, and it was one which contained a considerable amount of sodium bicarbonate in solution and was therefore distinctly alkaline. This water, when kept in contact with arsenical copper for 11 days, took up 0.003 mg. of arsenic per 100,000. With one day's contact no arsenic could be detected. The small amount of arsenic allowed in the copper used can therefore be considered as without effect. Experiments made with "drawn" copper and "rolled" copper, both arsenical and non-arsenical, did not show that any one kind was preferable to another so far as the action of water thereon was concerned.

Conclusions.

Summarised briefly, the conclusions arrived at are:—1. That copper is far less acted upon by water than is iron or lead. 2. That copper being vastly less deleterious than lead, copper pipes are far safer than lead pipes. 3. That copper pipes can be used for all waters which are not acid in reaction. 4. That acid waters should never be used until the acidity has been removed by treatment. Having been so treated copper service pipes can be used. 5. That practically all waters take up traces of copper if allowed to stand sufficiently long therewith, but that under all ordinary circumstances the amount taken up is far too small to endanger health.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

(Continued from p. 624.)

EVIDENCE OF THE HEARTS OF OAK SOCIETY.

THE first society to give evidence was the Hearts of Oak Benefit Society, which was represented by Mr. H. Dudley, Chairman of the Executive Council, and Mr. J. P. Lewis, the Secretary.

(Q. 2548-52.) The society has a membership of 433,000 insured persons and is administered under a centralised system with about 380 agents in the principal towns. The agents collect contribution cards and pay benefits; they also do sick visitation where men are concerned. Medical certificates and claims for benefit are dealt with at the head office. The society had a gross surplus of £728,000 at the 1918 valuation and a disposable surplus of £480,000.

The principal evidence of this society embodied recommendations as to the extension of medical benefit to the dependants of insured persons; the abolition of deposit contributors; the limitation of additional cash benefits; the provision of a specialist medical service for insured persons, and the inclusion of dental benefit as a statutory benefit under the Act. Their evidence also covered many recommendations on questions of machinery and minor matters.

Medical Benefit for Dependants.

(Q. 2553-61.) The witnesses suggested that medical benefit should be provided for the dependants of insured persons, broadly on the grounds that such extension is necessary for the improvement of the health of the community as a whole, and that the whole cost, which they estimated at a little more than 3d. a week per insured person, should be met by an increase in the weekly contribution, the increase to be borne wholly by the insured person. They estimated the cost at £10,000,000 per annum, and the number of dependants, they surmised, was 20 millions.

(Q. 2562.) Have you made any inquiry at all to ascertain whether the medical profession would be likely to accept the transfer of about 20 million patients from private to contract practice?—No.

Asked whether they considered that the large number of insured persons who had no dependants would accept a flat rate of contribution, and thus bear an equivalent burden with those who had dependants, the witnesses pointed out that unmarried men at present contributed towards maternity benefit, but they agreed (Q. 2622-6) that as this was a matter of ½d. a week as compared with a proposed 3d. it was not so serious a proposition, particularly in the case of women.

(Q. 2626.) Am I right in saying that single women who are employed are in much more danger of becoming dependent than having dependants?—Yes, that is so.

(Q. 2711-24.) Sir Alfred Watson questioned the witnesses closely as to the finance of their proposal, and they agreed that their estimate both as to the number of dependants and as to the cost per head might be under the mark. They therefore suggested that perhaps doctoring only might be provided and the free supply of drugs left for a later extension.

(Q. 2721.) Then you see no difficulty in providing medical attendance for the wife and children of an insured person and leaving that insured person to provide the

* In previous articles the proceedings of the Commission were reported under the following headings: Introductory Note; The Scope of the Insurance Scheme (see THE LANCET, Jan. 31st, pp. 247-8); The Provision of Medical Benefit (Feb. 7th, pp. 301-3; Feb. 14th, pp. 355-6; Feb. 21st, pp. 403-5); Financial Provisions of the Act (Feb. 28th, pp. 454-7); Medical Certification and the Regional Medical Staff (March 7th, pp. 508-9); The Approved Societies and the Money Benefits (March 14th, pp. 564-5; March 21st, pp. 623-4).

References to the official statement which has been issued as an appendix in four sections are given thus; Section A, para. 69, is shown as "App. A. 69," and references to the oral evidence thus—Q. 1369.

medicine himself, however expensive it may be?—... I admit that there is a difficulty; but I submit... that the difficulties which you suggest are out of proportion to what would actually take place.

(Q. 2722.) Having regard to the indulgent way in which the medical profession treat the families of the working classes, do you really think that the insured would be substantially better off under your proposal than they are at the present time?—Yes, I do.

As the cost to the State of the proposed extension would appear to be about £3,000,000 per annum, the question was asked whether the Society could show that insured persons generally were not in a position to provide medical treatment for their dependants. (Q. 2725-46.) The witnesses agreed that the present insurance system so relieved the insured persons as to enable them the better to pay for their families, but they thought the case for the extension of the benefit rested on the broad principle that a measure of health would be thereby secured for the insured men and women of the future.

Objections to a State Medical Service.

(Q. 2608, 2750-91.) The Hearts of Oak representatives were opposed to a State medical service. Their chief objections were that there would be (they assumed) no choice of doctor and that the doctors would work by the clock. A State medical service would, they thought, be a soulless service. They agreed that the administration of some of the local medical services—e.g., the tuberculosis centres, child welfare centres, and the school medical services—were good, and also that if a choice of doctor could be secured under a State scheme their objections would largely disappear.

Retention of Insurance Committees.

(Q. 2679, 3661.) The Society recommended the retention of Insurance Committees for the administration of medical benefit and said that they would have no objection to their administering dental or other treatment benefits.

Abolition of Deposit Contributors.

(Q. 2926-3129.) With regard to deposit contributors, who form that group of persons who do not join an Approved Society, the witnesses recommended that societies should be required to take over the whole of these persons, and that such persons should be compelled to become members of societies. The witnesses were examined at great length on this proposal. It was pointed out that deposit contributors were not a fixed number of the same people, but were constantly passing into Approved Societies and being replaced by new deposit contributors (the number of 1914 deposit contributors now remaining is under 50,000). (Q. 2984.) Further, that compulsory allocation amongst Approved Societies would involve the societies being deprived of their rights to expel members, so that the Rechabites might be compelled to retain a drunkard, a Catholic society to retain a Protestant, and a trade union society to keep a man who had gone over to another trade. The witnesses were not, however, disposed to vary their evidence in this respect, nor did they think (Q. 2942) that the allocation of a section of the population among societies which in many cases have social or trade qualifications would be a task of great difficulty.

(Q. 2999.) To abolish the deposit contributor class, and possibly get 100,000 people, at the most, distributed among societies, people who would not otherwise join societies—do you think for that they are going willingly to give up their right of expulsion in respect of all the unsatisfactory characters that might develop among 15,000,000 people?—Yes.

It was also elicited that insured persons, even if compelled to join societies, could not be compelled to accept benefits, and that many contribution cards might get destroyed and thus go to swell the amount of the Unclaimed Stamps Account.

Married Women.

(Q. 3205-3230.) The witnesses thought that married women were not a satisfactory insurance

proposition, mainly because of the difficulties of supervising sickness benefit claims.

Pooling of Surpluses.

The witnesses were of opinion that not more than 50 per cent. of a society's disposable surplus should be used for the provision of additional cash benefits, and they thought that societies might be compelled to devote the other 50 per cent. to treatment benefits without being logically obliged at a later stage to accept the loss of their discretion with regard to the administration of the whole of the surplus. (Q. 3240.) They were absolutely opposed to the pooling of surpluses in general, but would not object to some portion being pooled to ensure that all insured persons became entitled to dental benefit.

Dental Benefit.

The witnesses more than once impressed on the Commission the fact that there was a growing demand on the part of insured persons for dental benefit. They thought that at least one-half of the cost of dental treatment should be secured to the insured person and provided as a statutory benefit.

(Q. 3246.) Of all treatment benefits, in our opinion, the one most desired by the insured person, and also the most desirable from the point of view of the country at large, is dental treatment, and that we would take out of the category of additional benefits altogether by making it a statutory benefit. We would not allow it to be administered by the Approved Societies in the way it is at present.

(Q. 3248.) They suggested that the benefit might be administered through the Insurance Committee or through some body representing the dentists, the Approved Societies, and the Ministry of Health together.

(Q. 3648-9.) As there is much more room for individual fancy in regard to dental treatment than with regard to medical treatment, the suggestion was made that the scope of the benefit would have to be closely defined and a proportion only of the insured person's expenditure met.

The Panel Service.

(Q. 3711-55.) The Panel Service in the view of the witnesses is very much better than the service that was given to members of Friendly Societies prior to National Health Insurance, but at the same time it is nothing like what it ought to be; and in a great many instances the doctors do not give the same attention to people who are panel patients as they do to people who are paying them as private patients. They also suggested that in London, at any rate, the practice of referring patients to hospitals was too prevalent. They considered that all capitation fees for persons who had not chosen a doctor might be paid over to the hospitals notwithstanding that the panel doctors as a whole were at risk in respect of such persons. (Q. 3726-9.) If a person delayed choosing a doctor, he might reasonably be required to pay the doctor's fee for the first illness for which he required attention.

Specialist Services.

(Q. 3544-8.) The Society advocated the extension of medical benefit to include specialist services and considered that the cost of these services might be met out of the surpluses of Approved Societies.

(Q. 3547.) We thought that this specialist service, if possible, should be set up, and that it should be a first charge on 50 per cent. of the surplus of societies; and if it could not be paid out of that you might even draw on the other 50 per cent. We are quite prepared for that, and as we are not against some modified form of pooling of surpluses for treatment benefits, my Society, I am sure, would be quite prepared to pool a small part of its surplus to assist those societies that had not a surplus and could not give this service.

(Q. 3450.) Amongst other matters recommended by the Hearts of Oak witnesses were the adoption of the view of the Regional Medical Officer on a question of incapacity for work as definitely overriding that of the panel doctor where there is a

difference of opinion, and the inclusion of medical attention at confinements as part of the general practitioner service under the Act.

EVIDENCE OF THE ANCIENT ORDER OF FORESTERS.

The Ancient Order of Foresters is a registered Friendly Society administering National Insurance through 2130 of its branches (called Courts). It is the fourth largest Approved Society, having 737,577 members at the date of the first valuation and a disposable surplus of £629,800.

Form of Government.

There is direct representation from nearly every Court to a district meeting, held either half-yearly or annually, and direct representation is available from every Court to the High Court of the Order, which constitutes the annual meeting of the Approved Society. The Society claims that a large number of the members participate in the actual administration, and that the form of government accords most nearly with the principles upon which the Act was founded.

(Q. 3796.) A society of the type of the Foresters permits a personal association which is not possible in a large centralised society. The members themselves are enabled by reason of the constitution to take a more direct interest in their own affairs and in the management of their branches. We think, possibly, there is a more humane administration in a system such as we operate than there could be in a completely centralised system.

The Friendly Society Spirit.

(Q. 3183-5.) The Friendly Society or private side of the work still remains undiminished and is, in fact, larger than before the Act.

(Q. 3925.) You will remember that some years ago this matter was looked into, and your witness on that occasion told us that the old fraternal spirit was dying. He looked forward very pessimistically to the old spirit being eliminated with the State coming in, and he foresaw nothing but nationalisation. You would not put that forward to-day? —No; and I doubt very much whether the former witness would in view of events since that period.

Objections to Pooling.

(Q. 4003-4012.) The Society is entirely opposed to any complete scheme of pooling of funds, and is of opinion that such an arrangement would result in lowering the standard of administration and in consequence lead to a greatly increased drain upon National Insurance benefit funds. Any possible saving of expenditure on administration would be greatly outweighed by the increase of benefit expenditure due to lack of incentive to protect the fund.

(Q. 4022-5.) They saw no objections to the present system whereby some branches—e.g., in a mining area—having no surplus owing to the heavy calls to which they were subject, were unable to share in the surplus enjoyed by other more favoured branches. This has been accepted on the voluntary side for years.

Medical Benefit.

(Q. 4111-44.) The witnesses did not agree with the statement sometimes made that the service given to the insured population is of a lower quality than that given to private patients of the same class. It may be true in isolated cases, but they had rarely come across cases of dissatisfaction with any real substance in it. They thought that there might be more pooling of medical skill in particular areas and also that there should be greater facilities for more skilled diagnosis.

(Q. 4207.) With regard to the suggestion that doctors were too ready to transfer a troublesome patient to hospital, the reply was that very few concrete instances which could be sifted satisfactorily had come under observation. It was thought that there were more loose views on this particular subject than upon any other.

Medical Benefit to Dependents.

(Q. 4211-2.) This was a tremendous proposition, as to which there was a considerable diversity of

opinion among the members. In a general way they would like the benefit extended, but the financial commitments made it difficult to advocate this as a practical proposition.

Travelling Consultants.

It was thought that there was an ample margin in the present contribution to pay for a consultant service. But even if an increase were essential the service would be worth paying for.

(Q. 4113.) The skilled consultant in certain complaints could be, so to speak, put on wheels and instead of being at one centre be taken to various sub-centres on given days according to a time-table.

State Medical Service.

As to this the witnesses did not give expression to any pronounced views, and suggested that until the views of the medical profession on the subject were ascertained they would hesitate to express any opinion.

Dental Benefit.

(Q. 3951, 4119, 4171-7.) In the view of this society dental treatment should be given as a statutory benefit. It should have the effect of conserving the funds of the societies and should be paid for as far as practicable by applying a part of the contributions to a central fund, thus restricting the societies' surpluses. Expenditure incurred by a member, say up to £1, should be met in full, but the service, though valuable, should not be given if it involved increasing the contribution.

(Q. 4172.) In other words, you would, if necessary, curtail the dental service which you think ought to be supplied because of cost?—Yes. Cost is a great consideration. There is a limit beyond which the insured person should not be mulcted for insurance contributions. There is quite a considerable volume of opinion that that limit has already been reached.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE annual meeting of the President and General Council of this Fund was held at St. James's Palace on March 17th, when the accounts and report for the year 1924 were adopted. The Prince of Wales occupied the chair.

Lord Revelstoke, the hon. treasurer, in moving the adoption of the account of receipts and expenditure and the balance-sheet, which were subsequently passed, said that it was a source of gratification to the Council that the income for the year 1924 exceeded the estimates submitted to the Council in November last. There was one item in the receipts which would seem to call for special mention—namely, that of "donations," the total of which figured as £22,659. This sum included two anonymous gifts, one of £5000 and one of £7000, without the receipt of which the distribution of £235,000 could not have been provided from the annual income. For the year 1925 the Fund has already received one donation of £5000 from Lady Strathcona.

The General Position in 1924.

Lord Stuart of Wortley, chairman of the Management Committee, moved the adoption of the annual report, which stated that the year 1924 was the first since 1919 in which the voluntary hospitals of London did not receive any assistance from exceptional distributions towards meeting their maintenance expenditure. They had received in 1923 the final instalments of the money collected by the combined appeal which began in 1922. The financial position, leaving out of account all the special distributions, had continued steadily to improve. The net aggregate annual deficit had declined from £381,000 for the year 1920 to £175,000 for the year 1922, and for the year 1923, although there were still 54 hospitals whose income did not meet their expenditure, there

was a net aggregate surplus of £227,000. The last figure took into account an exceptionally large legacy of £247,000; but even apart from this, the net aggregate annual deficit for the year 1923 was reduced from £175,000 to £20,000. In these circumstances the question of the need for hospital extensions, which had been generally postponed since the outbreak of war, began to come to the front.

The total receipts of the King's Fund for the year were £412,472 4s. 1d., of which £112,240 was from the estate of the late Mr. John Wells; £50,203 1s. 9d. from the estate of the late Sir Thomas Sutherland; £16,000 from the estate of the late Mr. Samuel Lewis; £19,563 8s. 6d. from other legacies; £122 15s. 5d. from gifts to capital; and £214,342 18s. 5d. from general receipts. The amount contributed by the League of Mercy was £14,500, as in 1923. The total received by the Fund from the League since its foundation in 1899 was now £368,000, apart from the sums awarded by the League to institutions outside the area of the Fund's distribution. During the year the amount spent on administration was £10,614 16s. 11d., or £2 11s. 5d. per £100 of the total received, as compared with £8904 17s. 6d., or £2 1s. 4d. per £100, in the previous year.

Sir John Bland-Sutton having seconded the resolution, the report was adopted.

Work of the Propaganda Committee.

Sir George Lawson Johnston, chairman of the Revenue Committee, presented the report of the Committee on the work of the Propaganda Subcommittee, and moved the recommendation that it be published in the annual report of the King's Fund for the year 1924. This Committee, the report stated, under the chairmanship of Lord Burnham, was appointed in 1923 as a subcommittee of the Revenue Committee, with a two-fold object—viz., to consider and promote schemes for raising money for the King's Fund in the fields of education, art, science, literature, and law, in general continuance of the work of the Education Auxiliary of the Combined Appeal; and to organise general propaganda of the work of the King's Fund and the voluntary hospitals of London. The Committee had been largely engaged in schemes of direct propaganda not aiming at any immediate financial return; and even in the money-raising schemes the amount and value of the publicity to be obtained had been taken into account quite as much as the profit to be expected. The total receipts from this source were £1864 19s. 8d.

The adoption of the report was seconded by Lord Burnham and carried.

Report of Management Committee on the Distribution of the Wells' Legacies and Ambulance Cases Disposal.

Lord Stuart of Wortley presented a report of the Committee on the Wells' Legacies Distribution, and the Ambulance Cases Disposal Committee's report, and moved recommendations. He said: 1. In connexion with the special distribution in aid of extensions and improvements, out of the legacies of the late Mr. and Mrs. John Wells, the Council in December last approved grants amounting to £81,000 for schemes which would provide 301 additional beds, of which 53 would be reserved for accident cases. 2. Of these beds, 54 have been opened during the last six months, including 24 for accident cases. 3. Arising out of the Ambulance Cases Disposal Committee's inquiry and report, but without financial assistance from the King's Fund, provision has been made for a further 20 beds for accident cases, making 44 accident beds opened to date. 4. Schemes are also being prepared which will provide yet a further 39 accident beds, making 112 in all. 5. The Management Committee consider that it would be desirable for the special powers of the Distribution Committee in this matter to be continued.

6. Recommendation No. (i.) of the Ambulance Cases Disposal Committee's report, on the subject of the provision of accident beds, is thus being put into operation by the Distribution Committee. Recommendation No. (ii.), on the subject of the lists of voluntary hospitals and Poor-law infirmaries to which ambulance cases should in the first instance be taken, is being carried out by the London County Council, the King's Fund, and the Ministry of Health. The Management Committee were informed in July last that Recommendation No. (iii.), on the subject of the law or procedure applying to Poor-law infirmaries, was under the consideration of the then Minister of Health, and they think it desirable that it should be brought to the notice of the present Minister of Health.

The Management Committee accordingly recommend—1. That, in connexion with the Wells' Legacies distribution, the Distribution Committee should be authorised to entertain further proposals on the lines approved by the Council in July, 1924, with power to act in cases where, for reasons of urgency, it is desirable to take action in advance of the Distribution Meeting of the General Council next December. 2. That a letter be written to the Minister of Health in the name of the Council drawing attention to the correspondence with the former Minister of Health on the subject of Recommendation No. (iii.)¹ of the Ambulance Cases Disposal Committee report, and expressing the hope that action will be taken.

The recommendations, having been seconded by Lady Hudson and supported by Sir William Collins, were carried unanimously.

The Prince's Speech.

H.R.H. the Prince of Wales said that he had already reviewed the events of the past year,² but had much to add to that summary. The accounts had come out rather better than the estimates, and that was encouraging for 1925. One thing was certain: the claims on the King's Fund would go on increasing. The first instalment of the Wells' Legacies distribution would help to provide 300 additional beds, and they would all have to be maintained; and there were more extension schemes coming along. Then the enlargement of the Fund's area to 11 miles from St. Paul's had already brought in 14 more applications. So the King's Fund and the hospitals would need increased income; and, if the progress of these last few years was any guide, they would get it, if only the public realised the need. This was where the value of our propaganda work came in. The Special Committee with Lord Burnham as chairman, and Prof. Winifred Cullis as vice-chairman, were making the name of the King Edward's Hospital Fund familiar where it was hardly known before, and, along with that, they were spreading a knowledge of the work of the hospitals which it was hoped would bring in a bigger income for the hospitals as well as for the Fund.

The report of the Ambulance Cases Disposal Committee continued to bear good fruit. Forty-four additional accident beds had been opened; and the Wells' Legacies grants would help to add others. When all the schemes that had already come before the Distribution Committee were carried out, there would be 112 more accident beds in London than there were when the inquiry began.

To a vote of thanks to the Prince of Wales, moved by the Hon. Sir Arthur Stanley and seconded by Sir William Church, His Royal Highness briefly replied.

The Propaganda Committee of King Edward's Hospital Fund for London has arranged a third series of lectures and counter-lectures to be held immediately after Easter in the Great Hall of the London School of Economics, on Tuesdays, at 5.30 P.M.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.

POST-GRADUATE TEACHING IN LONDON.

A DISCUSSION on post-graduate teaching in London took place at the Royal Society of Medicine on March 18th, under the auspices of the Fellowship of Medicine and Post-Graduate Medical Association. Sir Arbuthnot Lane, President of the Fellowship, was in the chair, and opened the debate by describing the inception and success of the movement. "Post-graduate education," he said, "is a habit which every medical man must acquire if he hopes to succeed in his profession and gain the confidence of the public."

Mr. H. J. Paterson said that the meeting had been called to receive from those present criticism and suggestions. The Association had been founded in 1918 and there were at the present time 40 hospitals associated with it. General course-tickets were obtainable for any period from two weeks to several years, while there were short general courses, refresher courses, and courses in special subjects, while appropriate lectures were delivered in the Royal Society of Medicine from time to time which were open to all members. The aim of the Association was to make London a great centre of post-graduate education for the world, and to encourage the post-graduate habit in British medical men. In America, he said, every self-respecting doctor attended a course at least once a year. Since the inception of the Association £7000 had been distributed by it to the different hospitals. The organisers wanted now to find out what more they could do to meet the needs of post-graduates.

Surgeon-Commander T. Brown Shaw spoke on behalf of the Navy, in which service every medical officer was obliged to pass an examination before promotion to the rank of Surgeon Commander. This requirement involved a five months' course of post-graduate study, three months of medicine and surgery, now taken at the London Hospital, where arrangements were made to meet their particular needs, and two months at the Greenwich Naval Medical School, studying such special subjects as naval hygiene, bacteriology, &c. Courses in tropical medicine were provided at the London School of Tropical Medicine. After 14 years' service it was customary, though not compulsory, for men to take a three months' course in general medical knowledge with special attention to any subject in which they wished to specialise. Seventy-one officers had taken such a course in the three years 1922-24. In this connexion the assistance of the Fellowship of Medicine had been valuable and the facilities provided most satisfactory. The needs of naval men lay chiefly in the realms of neurology, psychological medicine, balneology, dermatology, ophthalmology, and operative surgery. Centralisation would not be of value; it was better to have the work scattered over many hospitals. More clinical work might advantageously replace some of the lectures. The classes were apt to be crowded and further opportunities for operative surgery would be welcomed.

Sir William Leishman described the measures taken for post-graduate study in the Army, which had not yet made use of the Fellowship of Medicine. The Royal Army Medical College provided instruction for young officers and a refresher course for the seniors. A senior course of six months' instruction was compulsory, and the career was punctuated by examinations, on which the future of the officer might depend. The course took place about the tenth year of service—i.e., usually at the close of the first period of foreign service—and on an average 30 captains attended each year. The first part of the course consisted of medicine, surgery, pathology, and State medicine, mostly in lecture form, supplemented by attendance at cattle-markets and recruiting stations. The second part of

the course was more clinical and men were able to attend Charing Cross and St. Thomas's Hospitals. Those who showed satisfactory examination results were then given a chance to qualify as specialists in medicine, chiefly tropical, operative surgery, pathology, ophthalmology, ear, nose and throat, obstetrics and gynaecology, dermatology, including venereal diseases, radiology, anaesthetics, mental disease, or hygiene. With some of these subjects the College itself dealt satisfactorily; for others the men went to special centres, such as Bethlem Royal Hospital, and were encouraged to take the higher degrees and diplomas, such as F.R.C.S., D.P.M., and D.P.H. No expense was incurred by the officer in question; the State in this respect was no ungenerous master.

Dr. G. E. Orme spoke as a general practitioner of 25 years' experience who had recently taken up residence in London and associated himself with the Fellowship of Medicine; he found it difficult to speak too highly of the value of the work and the kindness of the administrators. He considered that it had proved itself to be an institution of national importance. If any criticisms were to be made he would refer to two which were commonly heard, though perhaps rather baseless. One was that strangers coming to London were at a loss to know where to go, and when they did arrive at hospitals no one took any notice of them, and they were apt to feel rather out of it. Possibly certain consultants or junior members of staffs would allow their names to be put on a panel and would be personally responsible for arranging tours round hospitals and collecting for demonstration cases suitable as subjects for diagnosis and treatment by every modern means of investigation and therapeutics. Another suggestion he would make was that there should be association between the Fellowship and the provincial post-graduate centres. Some men might wish to take a part of their course in London and a part in some other district of England. Perhaps also there might be some arrangements made for parties to visit important instruction centres abroad, a plan widely adopted in America.

Mr. Zachary Cope urged the institution of some scheme whereby every medical man who needed a refresher course should have some means of obtaining it. Many could not afford either the time or the money; there should be some grant, perhaps from the Government, to form an inducement to every doctor to improve his mind.

Dr. Muriel Lane, speaking as a woman post-graduate, said that what the women chiefly needed was instruction in diseases of women and children and in preventive medicine. Excellent courses of diseases of children had been held, and of particular value were the round-table discussions of differential diagnosis, which might well be extended. The gynaecological courses were too infrequent. There were many difficulties in the way of providing the practical experience needed in obstetrics, gynaecology, and venereal disease, but at least there might be courses of lectures in antenatal and postnatal care, and infant welfare clinics might be added to the list of places to be attended.

Dr. Sophia Jevons spoke as a practitioner living in London who was busy till 5 o'clock every day; she thought that for such as herself the most valuable provision would be a clinical lecture going on some four nights every week to which they could come when able. The London doctor did not want an intensive course to which he had to give up all his time. She was surprised to hear a suggestion of Government subsidy having regard to present taxation.

Dr. H. B. Newham referred to his experience at the London School of Tropical Medicine as post-graduate and teacher of post-graduates. He was sure that the Association was doing its level best, but the teaching itself was the source of the trouble. He was informed that in America no man, however brilliant he might be, had a chance of getting on to

the staff of a teaching hospital unless he could teach. This was not the case in London; many of the best clinicians were quite unable to impart information and would not try to learn the art. The average student loathed lectures, and what was wanted was more experience in practical work. Moreover, there seemed no arrangement for deputising; in his experience the chief was often detained or prevented from coming, and the student who had, perhaps at great inconvenience, attended at the stated time, was left without anybody to take him round. In many clinics there were far too many cases; the person in charge had no time for systematic teaching as he had to get through all the cases somehow. There was a tendency to dwell on rarities; the post-graduate needed instruction on bronchitis far more than on pseudo-hypertrophic pulmonary osteo-arthritis.

Dr. M. B. Ray asked whether the wealth of material available had been used to the best advantage. There were two classes of post-graduates—the casual, those resident in London doing extra work in their spare time, and visitors from abroad combining instruction with sight-seeing. These were admirably provided for. The second class, small perhaps now but of immense potentialities, consisted of those who wanted to spend some four to six months in real study. It would be a good thing if every doctor were bound to take a refresher course after a certain period in general practice. These at present could return to their old medical school, but this was not satisfactory, and the intensive courses provided were too short. There ought to be a thoroughly up-to-date and well-equipped post-graduate school, with its own teaching staff and attached hospital. Examinations taken at the end of the course should entitle successful candidates to a registrable diploma. He asked whether it were not possible that one of the undergraduate schools might close its doors to all but graduates and form the nucleus of such an institution.

Dr. Fortescue Fox said that the old Society of Balneology had engaged in post-graduate teaching of its subject; when it was amalgamated into the Royal Society of Medicine this activity ceased; he suggested that the present Section of Balneology and Climatology should be allowed to give their serious attention to the teaching of these subjects.

Mr. E. B. Turner referred to the suggestion that practitioners should take part in public health work and said that in this way doctors could combine post-graduate instruction with valuable civic service. Public health work was tending to fall more and more into the hands of whole-time officers, often very recently qualified. General practitioners should work more in municipal clinics, and, where possible, secure election to borough councils and health committees; they could also assist public health by lecturing and teaching, for they would teach themselves at the same time.

The discussion was adjourned to a date provisionally fixed for April 8th.

THE HEALTH OF THE ROYAL AIR FORCE.

THE report on the health of the Royal Air Force for the year 1923 has just been issued.¹ Excluding minor cases of disablement of less than 48 hours' duration, the ratio of fresh cases of admission to hospital per 1000 strength has reached the lowest point so far reported, and the death-rate, the invaliding-rate, the average number of days sickness per individual, and the ratio of the number of sick daily are also the lowest so far recorded. The number of cases of disablement of 48 hours' duration, due to common colds, slight pharyngitis, and nasopharyngitis, show an increase,

believed to be caused by the fact that 1923 was the wettest year on record since 1916.

When the separate diseases are analysed an increasing percentage of total invaliding for tuberculosis is revealed: a disquieting feature which is being specially investigated. The case incidence of venereal disease is slightly lower than that for 1922, and this is principally due to a reduction in the readmission-rate suggesting that treatment has become more effective. Upper air-passage infections also show a reduction. Injuries are grouped under the headings of those occurring while on duty and those due to athletics or accidents while off duty and on leave. The injuries due to flying have remained at an almost constant figure of just over 6 per cent. of the total injuries during the last three years, which is considered satisfactory in view of the fact that there has been a progressive increase in the number of hours flown during these three years. The nosological tables have been still further abridged as compared with previous years and require very little explanation in the text.

The Air Force Abroad.

The health of the Air Force abroad is, as usual, made the subject of a separate chapter, and here again the admission-rate, the death-rate, the average number of days sickness per individual, the ratio of the number of sick daily, and invalids from the service are the lowest on record. Sand-fly fever continues to be responsible for a large amount of sickness, especially in Iraq, although a considerable reduction has been effected in the case incidence-rates in each individual area except Malta. The disease appears to vary in intensity from year to year so that it is difficult to estimate how far such a reduction is due to prophylactic measures. Malaria has increased in incidence in most areas: in the case of the Mediterranean Littoral this is explained by an undue proportion of men exposed to infection for the first time, but, on the other hand, in the Basrah district of Iraq, blame is laid on the impossibility of carrying out preventive measures on anything like a large enough scale. In all units a vigorous anti-malaria campaign was prosecuted but without producing the hoped-for results on the case incidence. Dysentery, on the other hand, has continued to decrease, and taken as an index of sanitary efficiency among units stationed in tropical countries, this is very satisfactory.

An interesting feature of the report on the health abroad is an account of the transport by air of 200 cases of diarrhoea and dysentery which occurred amongst a column of British troops operating in Northern Kurdistan. The only available transport consisted of pack animals, so aeroplanes were despatched from Baghdad to deal with the situation and, despite exceptional difficulties and one "crash," fortunately without any untoward result, 198 cases were successfully carried all the way to Baghdad.

Miscellaneous.

A chapter with this heading deals with the work of the Central Medical Board and the results of examination for physical fitness both of recruits and of officers are analysed in instructive tables. Under the heading of hygiene and sanitation the various measures instituted for preserving the health of the Air Force, both at home and abroad, are fully set out. Further tables summarise the laboratory work and the surgical operations carried out at R.A.F. hospitals, together with the dental treatment provided during the year 1923.

CARDIFF ROYAL INFIRMARY.—This hospital of 310 beds has a waiting list of 1806. The number is swollen by the necessity of taking in street accident cases which are growing rapidly. To meet the difficulty to some extent it has been arranged, with help from the Rockefeller grant to the Welsh National School of Medicine, to buy a house for the accommodation of some of the nurses, whose present dining-room in the hospital is again to become a ward. Patients who do not belong to the contributory fund last year contributed just under £4000.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Results of Attempted Rejuvenation.

IN an interesting review covering the whole field and literature pertaining to the problem of sexual rejuvenation by means of surgical interference, Dr. Wilhelm has pointed out emphatically that the original enthusiasm over the boon conferred upon mankind by Prof. Steinach and his collaborators has given way to profound silence. Prof. Steinach at first believed that in the genital glands there existed two groups of cells or glands distinct as regarded their function. One was the "gland of puberty," which was supposed to be subject to hypertrophy if the other part, the "progenitory gland," was eliminated by ligation of the vas deferens. Several medical men of ripe age, amongst them Prof. Zeissl (who died recently in Vienna), underwent this operation and published the results obtained. Prof. Romeis is also strongly opposed to the views of Prof. Steinach. Prof. Zeissl published in the *Wiener Klinische Wochenschrift* an autobiographical account of the operation and denied absolutely that it had any of the effects of rejuvenation of his own body, as had been claimed by the "youth restorers." In all the cases of rejuvenation of rats, reported by Steinach, Kammerer, and Voronoff, an improvement of the general condition could be observed after the operation, but the effect was only temporary. After some time the old conditions returned, in some instances even there was distinct deterioration. The return or increase of sexual desire and function could not be proved to be other than a psychic one. Prof. Leschke, of Berlin, was able to demonstrate that the ageing of human beings was dependent not only on the interstitial substance of the testicles, but also on the other inner secretory glands. When it was finally shown by Harms and Romeis that an old male rat could be made to produce long glossy hair, not only by transplantation of testicles, but also of fragments of liver tissue, it became evident that a large proportion of all the "rejuvenation" symptoms were simply caused by reabsorption of non-specific products of metabolism from the transplanted material. Also the use of X rays and of diathermy on the female genital glands, so much in vogue for some time as methods of rejuvenation of the female organism, has become quite obsolete; nor have the original attempts at curing sexual perversion (homosexuality, sadism) by means of transplantation of genital gland tissue been successful. Dr. Lichtenstern reports on 22 cases of such attempts, and is forced to admit that the effect had been rather "overrated." It is therefore questionable whether we are altogether on the right track in trying to obtain a "prolongation of youth" by these means, or whether it is only a faulty technique that is responsible for the unfavourable results.

The Problem of Sleep.

At a recent meeting of the Biological Society of Vienna Prof. Economo discussed the problem of sleep. The outcome of all investigations into this problem is that we do not know yet why we sleep. Neither the theory of changes of the circulation in the brain nor that dealing with toxic substances produced by fatigue is satisfactory. If impressions from the outward world are withheld we may easily fall asleep. But it seems that there is a certain sleep-control centre in the brain which regulates—in a periodic way—sleep and wakefulness. The action of certain hypnotics, as well as somnambulism, shows that sleep is not a negative but a positive function of the brain. In human beings sleep is in close connexion with the change of day and night, but such is not the case in many lower animals. Also the function of the hypophysis seems to pertain to sleep. Experimental pathology has, according to Economo, a vast and fallow field of research to dig on this subject.

Trephining amongst Prehistoric Races and Aboriginal Tribes.

In a very interesting paper read before the Vienna Medical Society Dr. Wölfel discussed the problem of trephined skulls so often found amongst prehistoric and aboriginal peoples. It is now accepted, he said, that some races (in America and in Melanesia) still use this method for treatment of certain diseases and conditions, and in both countries, so widely apart from each other, the same method is used for the same conditions; a certain degree of civilisation is required for the knowledge of the procedure; and the peoples practising it have reached the agricultural stage. The method is used for treatment of fracture of the skull; wounds of the temporal bones were, he said, not treated because they were regarded as lethal. The aborigines of the Bismarck Archipelago have a fair knowledge of treatment of such wounds. They perform a regular surgical operation with removal of injured skin, bone, and fragments; they even know how to search between the sulci of the brain for dislocated fragments of bone. They also know how to elevate depressed portions of bone. Also in brain diseases (epileptic fits, headaches, mental disturbances) trephining is practised, and the bone is "eroded" by means of sharp instruments. A bandage consisting of a charred leaf and strapping is then applied. The mortality is low, less than 20 per cent. In some places persons have been found who had this operation performed on their heads five or six times. It is safe to assume, continued Dr. Wölfel, that the prehistoric people, who have left us so many trephined skulls, performed this operation for the same reasons as those on which we now base our surgical operations on the cranium. The prehistoric surgeons also used to make a round, regular, thin-edged opening, no doubt with sharpened flints or bones; Hippocrates tells of this custom amongst ancient and "modern" barbaric races; whilst nowadays in Peru, in Central America, in the Australian and Polynesian islands the custom is still in force, showing that the trend of mental development was in the same direction amongst different races. Dr. Wölfel rejected the idea of these operations having been done for religious or superstitious reasons.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Records of the Metropolitan Insurance Company.

SPEAKING in Baltimore on Feb. 9th on the experience of life insurance companies in preventive medicine, Dr. Lee K. Frankel gave interesting records of the years 1911 to 1923 for which accurate statistics are available. During these years the difference between the mortality-rates of the insurance company and of the "registration area" show a saving of 200,000 lives among the policy-holders. This is the more remarkable in that a great deal of this company's work has been amongst workers in industry and their families. Dr. Frankel showed how much greater in 1911 was the risk of death in this group of policy-holders than in the general population. The two death-rates have converged since then, and if the present trends continue, should cross in about two years time. In 1928 it may be safer to be an industrial policy-holder in this company than to be a member of the general public. Dr. Frankel is satisfied that these results are attributable to the health measures inaugurated by his company. Education of the policy-holders both by literature, printed in many languages, and by nurses who also care for the sick, and free medical examinations for those who care to take them were the chief measures employed. Their cost amounted to about one-third of the saving in death claims, which is calculated at 42 million dollars. It is interesting that only 8 per cent. of the policy-holders have availed themselves

of the privilege of regular medical examinations. This group shows a mortality 28 per cent. better than that of the whole group of insured.

Typhoid Epidemic Traced to Oysters.

In a previous letter (THE LANCET, Jan. 21st, p. 252) I mentioned the unusual prevalence of typhoid fever in New York and Chicago and indicated the probability that the investigation undertaken by the Federal Health Service was likely to produce important results. This investigation has already been completed and a preliminary report given by Dr. L. L. Lumsden to the press. It will be some time before the complete report with all the circumstantial evidence can be published, but I am reliably informed that the evidence already obtained is unusually complete, as indeed it must be, to justify the statement that has been made public. The epidemic lasted for two months—from Nov. 15th to Jan. 15th. In this period the actual number of cases of typhoid exceeded the "expected" by 650 in New York, 100 in Chicago, and 50 in Washington. Several other cities have shown an excess number of typhoid cases during the same period. A careful epidemiological record has been made of 98 cases in Chicago and its vicinity, of 42 cases in Washington, and 263 in New York City. The chronology of the outbreaks clearly suggested a common factor in the distribution of the infection in all three cities. The preliminary announcement incriminating oysters is couched in the following terms:—

"The preponderance of evidence is that the general supply of no large distributor of oysters was uniformly infected, but that oysters infected in one or more beds, or part or parts of one or more beds, or at one or more floats, and constituting but a small proportion of the total, were introduced into and distributed with a large supply of oysters of good sanitary quality."

The source of distribution was definitely traced to a company at West Sayville, Long Island, that handles a popular brand of raw oysters. In the interest both of the public health and of the oyster trade it is recommended that provision be made at the earliest possible date for—

"more nearly adequate official sanitary supervision, regulation, and protection of industries engaged in the production, preparation for sale, and distribution in interstate traffic, of shell-fish, vegetables, fruits, milk, milk products, and other foods eaten usually or frequently without being cooked."

Not only the New York oyster industry has suffered but the whole industry of the Eastern shore. The Illinois Commissioner of Health, on what seems to have been very slight evidence, put a ban on the oysters of Maryland, Virginia, and practically ruined the trade in these States. It is now required that before the oysters are readmitted to Illinois careful tests be made to ensure that no typhoid carriers are engaged in the trade.

MEMORIAL TO THE LATE SIR WILLIAM MACEWEN.

A FUND was inaugurated in Glasgow on May 22nd, 1924, with the object (1) of providing a bust of Sir William Macewen for presentation to the University of Glasgow, together with a replica to be presented to Lady Macewen; (2) of endowing a Macewen Memorial Lectureship; and (3) if possible, of instituting a Macewen Medal or Prize in Surgery, to be awarded annually (see THE LANCET, 1924, ii., 32). The General Committee of the Memorial Fund hoped to raise the sum of £3000 and of this figure about £1550 have now been received, the list of subscriptions including names from all parts of the world. The list is still open, and any further subscriptions should be sent to the hon. treasurer, Mr. James Macfarlane, Wesleyan-street, Glasgow, S.E. We commend to our readers this project of raising a fitting memorial to a surgeon whose fame was world-wide, and trust that the full sum aimed at will be obtained, in order that the scheme may suffer no retrenchment through lack of financial support.

The Services.

R.A.M.C. OFFICERS.

ON Monday, March 16th, when the House of Commons went into Committee on the Army Estimates for 1925-26, Lieut.-Colonel Pownall drew attention to the shortage of officers for the Royal Army Medical Corps. Many officers whom the Corps would have been glad to keep on, he said, had resigned in recent years as they were not satisfied with regard to their professional prospects in the Corps and very few had been coming forward. Of 80 vacancies advertised during the past two years only 25 had been filled, and during the year since Jan. 31st, 1924, only one candidate had been gazetted into the R.A.M.C. The total establishment in England and abroad was 884, and the wastage was about 60 or 70 a year. Before the war the pay of medical officers was considerably more than that of combatant officers. Now, while the pay of combatant officers has been greatly increased, officers of the R.A.M.C. receive very little more than in 1914. Once again he reminded the House of Commons that officers in the R.A.M.C. do not get their commissions until they are 24, whereas those in the combatant ranks are gazetted at 19. And once again he suggested that the Secretary of State might consider the question of making the Director-General of Medical Services a member of the Army Council. Lord Esher's Committee some years ago recommended that course, which would give an extra status to the R.A.M.C., and permit the position of the Corps to be represented directly to the authorities. The Secretary of State for War, Sir L. Worthington-Evans, agreed with Colonel Pownall that the position of the R.A.M.C. must be most carefully considered, as the number of medical officers required were not obtained, and consequently a greater burden was being thrown upon those in the Corps than they ought to be asked to support. It was very largely a question of money and conditions of service and in that he was not complete master. The conditions in the Navy and the Air Service had to be considered at the same time, and he hoped that proposals would be brought forward shortly which would enable that position to be remedied.

We share the hope of the Secretary for War, but seem to have heard before promises of remedy to be brought forward shortly. The Services, moreover, are not so much in competition with each other in respect of pay as with lay bodies offering larger pecuniary reward to medical careers that are attended with less sacrifice.

ROYAL ARMY MEDICAL CORPS.

Capt. W. H. Ferguson is granted the temp. rank of Maj. whilst empld. as Dep. Asst. Dir. of Pathology.

Capt. W. H. Dye is restored to the establishment.

TERRITORIAL ARMY.

Maj. A. J. Brown to be Lt.-Col. and to command 155th (Lowland) Field Amb.

Maj. A. E. Evans from Sanitary Companies to be Maj.

Capt. A. E. Chisholm resigns his comm. and retains his rank.

Lts. J. Robinson and H. B. Logan to be Capt.

J. J. Dykes Naismith to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

G. K. Foster to be Lt.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 14TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 137; scarlet fever, 1508; diphtheria, 883; enteric fever, 42; pneumonia, 1395; puerperal fever, 38; cerebro-spinal fever, 8; acute poliomyelitis, 2; acute polio-encephalitis, 2; encephalitis lethargica, 55; dysentery, 14; ophthalmia neonatorum, 141. There were no cases of cholera, plague, or typhus fever notified during the week. The number of small-pox cases showed a decrease of 198 from the number for the preceding week. Twenty-eight cases were notified from Derbyshire, 20 from Leicestershire (Leicester C.B., 20), 28 from Northamptonshire (Kettering, 26), 14 from Northumberland, 8 from Notts, and 30 from Yorks, North Riding (Middlesbrough C.B., 29).

Deaths.—In the aggregate of great towns, including London, there was 1 death from enteric fever, 100 from measles, 17 from scarlet fever, 104 from whooping-cough, 47 from diphtheria, and 283 from influenza, as compared with 361, 346, 352, and 354 in the four preceding weeks. In London itself the deaths from influenza numbered 36, from whooping-cough 30, and from diphtheria 13.

HEALTH STATISTICS OF THE MERCANTILE MARINE.

To the Editor of THE LANCET.

SIR.—Will you permit me to comment on Dr. E. T. Burke's letter, under this heading, in your last issue? If some of us hesitate about the Board of Trade's conscience—all of us are, unhesitatingly, with Dr. Burke on the side of the sea-farers. Everyone will agree with him that there should be in every port a V.D. treatment centre easily and quickly got at, and at any time on any day, for sea-farers. I submit this centre need not be actually in the docks. That the centre should be for the use, comfort, and aid of the sea-farer exclusively is surely unnecessary. Many years' experience of sea-farers who had sailed to the wilderness of Zin and pitched in Mount Hor convinces me that they are not so exclusive as all that. Moreover, there is that considerable body of men who alternate between shore, dock, and ship jobs; they could hardly be placed in an in-and-out category in relation to treatment at the V.D. centre. The centre should have in-patient accommodation for sea-farers. With very few exceptions the sea-farer on being paid off his ship prefers not to come into hospital for V.D. treatment while his money lasts. When he has no money left he will, sometimes, ask to come into hospital to complete treatment; but more often he signs on a ship again and continues treatment, more irregularly than regularly, from port to port. It is reasonable to believe that with greater facilities for treatment at home and foreign ports this would become less irregular. At foreign ports such facilities are increasing; many of my patients inform me of the advantage they had taken of them. Actually it must be rare for a crew to be signed on a British ship in a home port unless they have passed the doctor, and my experience is that in the Port of London the examining doctors have keen eyes for indications of V.D. Very many of my patients have failed to pass the doctor; some of them turn out not to have V.D. I believe Dr. Burke overestimates the docility of the sea-farer and the ingenuousness of those in control of ships. The first would not consent to the certification (though their confession to the hospital doctor is frank and ready) about exposure to infection and "prophylaxis." The latter would not sign on anyone, cleansed and injected, or not, about whom there was an agreed and confessed chance of developing V.D. on the voyage. Besides the possible liability for the contagion of others of the crew, there are the passengers' susceptibilities to consider; with any such certification scheme owners could hardly plead their masters' ignorance of the risk of developing V.D. by the certificate-carrying sea-farer, and V.D. is never so hateful as in its early stages and in someone else.

Notices giving information about V.D. treatment centres are posted in ships and in the London Docks; perhaps more might be done in this line. Ship-masters and surgeons are, in fact, informed of these centres. The Port of London draggles on for some fourteen miles of river. Transport between its ports is unspeakably slow and bad. Its V.D. problem is one for several centres. While hospitals in general have, in the past, spurned landsman and sea-farer suffering from non-respectable V.D. (V.D. in the communicable stage), in the Port of London the Seamen's Hospital Society has always succoured and treated the V.D. sea-farer—even taking him into hospital. On any day and at any time the Dreadnought Hospital at Greenwich and the Seamen's Hospital, Royal Albert Dock, have always treated, as in- and out-patients, the V.D. sea-farer of whatever race, nation, colour, or creed; and still do so. Lastly, the second of these hospitals fulfils

one of Dr. Burke's requirements in being situated in the docks—ships berth not a hundred yards away.

I am, Sir, yours faithfully,

H. M. HANSCHILL,
Pathologist and M.O. i/c V.D. Clinic, Seamen's
Hospital, R.A. Dock.
March 23rd, 1925.

To the Editor of THE LANCET.

SIR.—With reference to the letter from Dr. E. T. Burke that appeared in your issue of March 21st, it is well to point out that in London the care and treatment of sailors suffering from venereal disease is not neglected. Attached to the Seamen's Hospital Society are two venereal clinics, one at the Dreadnought, Greenwich, and the other at the Seamen's Hospital, Albert Dock. At the former there were treated last year 1189 new patients and of this number 80 per cent. were seamen. At the latter 778 were treated, 50 per cent. of these being seamen. At Greenwich no less than 25 per cent. of the sailors were afforded the benefit of in-patient treatment, and at the Albert Dock 15 per cent. were admitted to the wards.

While one realises the great advantage to be derived from placing a centre in every dock, where it is easily accessible to the incoming sailor, this would lead to a multiplication of clinics which would be practically impossible. Of the two clinics mentioned one lies immediately between the Albert and Victoria Docks, while the other is in close proximity to the Surrey Commercial Docks, and the Society is so well known that sailors gravitate to these centres, not only from every dock on the Thames, but from every outport in the Kingdom.

Should the patient be forced by circumstances to go to sea again before his cure is complete he is given a transfer book detailing the treatment he has already received and instructing him where to get further treatment in other ports.

It would be well to remember that this Society is a pioneer in the treatment of venereal disease, which was carried out efficiently before the Venereal Diseases Act was passed.

I am, Sir, yours faithfully,

P. J. MICHELLI.
Seamen's Hospital, Greenwich, S.E.,

THE MEDICAL WITNESS.

To the Editor of THE LANCET.

SIR.—In your issue of Nov. 22nd last Sir William Willcox is stated to have said during the discussion on the Medical Witness at the Hunterian Society "the expert witness should be in court during the whole of the proceedings. Indeed, it had been ruled that it was necessary for such a witness to hear the evidence." Will Sir William Willcox kindly give others and myself through your columns the reference to the ruling he quotes? I ask this because in a recent case of criminal abortion where I was called in, when the trial came on all the witnesses were told to retire. I at once asked the magistrate if such instruction applied to the medical witness also, and he promptly replied "Yes." Of course, here in Victoria things may be different, but the general principle should apply. Thanking Sir William Willcox in anticipation,

I am, Sir, yours faithfully,

Melbourne, Victoria, Jan. 27th, 1925. JAMES BOOTH.

** We have referred Dr. Booth's letter to Sir William Willcox and the following is his reply:—

"Regarding the point raised in Dr. Booth's letter, it has been the usual custom in this country for the expert witness for the Crown to remain in court during the whole of the proceedings. I am referring, of course, to cases in which the evidence of the expert may be required on any point which may arise during the hearing of the case. For example, in toxico-

logical cases it is necessary for the expert witness to hear the evidence relating to the symptoms from which the poisoned person suffered, since he may be required to express the opinion as to whether these symptoms are, or are not, consistent with poisoning by a particular substance.

"During an experience of 20 years it has been my custom, if giving expert evidence in a case, to be present in court during the whole of the proceedings. Indeed, I have often been asked by opposing counsel if I have been present since otherwise my evidence would have been objected to. It must be clearly understood, of course, that individual cases vary and that the presence of an expert witness in court is always subject to the discretion of the Judge. A legal authority has kindly quoted various rulings relating to this subject.

Some Legal Rulings.

"There is not in substantive law, that is, by Statute, any provision regulating the permitted presence or the ordered withdrawal of witnesses on either side from a court during a trial, but the practice appears to be as follows:—

"At any time during the course of a trial and on the application of either party, the Judge may order in his discretion witnesses in the case to leave the court, and it is not a matter of right in either party to obtain such an order. In criminal trials a prosecutor is entitled to remain in court only in his capacity as prosecutor, but if he is a witness also he may be ordered to retire. A solicitor in the case, though a witness, is usually permitted to remain for the purpose of instructing counsel, &c., and it is the usual practice for witnesses who are called to give expert evidence and not to speak to facts only to be allowed to remain even although other witnesses are excluded. If a witness does remain notwithstanding an order, his evidence is not rendered inadmissible, but is the subject of comment.

"As to expert witnesses, the question of whether they may be allowed to remain in court to hear the evidence is now a matter which is decided by the kind of questions which may be put to the expert witness and which assume that he has heard the evidence in the case. It will be recollected that the fifth question in *McNaghton's* case was 'whether the medical man conversant with the disease of insanity who never saw the prisoner previously to the trial, but who was present during the whole trial and the examination of all the witnesses be asked his opinion as to the state of the prisoner's mind at the time of the commission of the alleged crime,' and the answer of H.M. Judges was, 'We think the medical man under the circumstances supposed cannot in strictness be asked his opinion in the terms above stated, because each of those questions involve the determination of the truth of the facts deposed to which it is for the jury to decide, and the questions are not mere questions upon a matter of science in which case such evidence is admissible, but where the facts are admitted or not disputed, and the question becomes substantially one of science only, it may be convenient to allow the question to be put in that general form, although the same cannot be insisted on as a matter of right.'

"In a case of *R. v. Wright*, Russell and Ryan 456 (1821), about 20 years before *McNaghton*, a medical witness was allowed to discuss the facts of the case, the absence of motive, the appearance and behaviour of the prisoner, that he had drink, that he threw a boy into the water, that he did not recollect some of his actions at one time, but recollected them at others—and to express the opinion that the prisoner's mind was disordered. The report does not record whether this gentleman was in court and heard the evidence, but I gather that he was; he could hardly otherwise have obtained all the details which he discussed. The Judges on appeal were somewhat doubtful, but decided that the witness of medical skill might be asked whether such and such appearances or whether such and such actions were symptomatic of insanity. I think this case has been somewhat qualified by the above quotation from *McNaghton*.

"In *Frances*, 4th Cox 57 (1849), a doctor who had been in court throughout the trial was called and asked whether having heard the whole evidence, he was of opinion that the prisoner was of unsound mind at the time of the offence, and the answer above quoted in *McNaghton* was discussed, and it was laid down that the proper mode is to ask what are symptoms of insanity, or to take the particular facts in the case and assuming them to be true to ask whether they are symptomatic. The question here sought to be put really substituted the witness for the jury.

"In *R. v. Searle*, 1 Moody and Robinson 75 (1831), a physician who had heard the whole evidence was asked to give his opinion as to the insanity of the prisoner. The Judge doubted whether this could be done, but on referring

to *R. v. Wright* above quoted, he allowed him to be asked whether the facts and appearances proved showed symptoms of insanity.

"In 2 Russell on Crimes, eighth edition, p. 2142, a note by a great authority, the late Mr. C. S. Greaves, reads as follows:—'It is now the ordinary course to permit not only attorneys, but professional or scientific persons to remain in court, the rule being considered as not applying to witnesses of those descriptions.'

"In a comparatively recent case of *R. v. Mason*, 76 Justice of the Peace, 184 (1911), Mr. Pepper, who had not seen the body or the wound, but had heard the evidence given by the doctor who had seen the body, after reading the depositions, was asked, and allowed to answer after objection, his opinion as to whether the wound was self-inflicted or not, and *Frances's* case above quoted was cited in the Court of Criminal Appeal. Lord Alverstone said 'the point raised is of importance' and approved of the admission of Mr. Pepper's evidence as being the opinion of an expert witness on assumed facts.

"In Archbold, 26th edition, 451, it is stated that 'symptoms being proved, a physician may be called upon to give in evidence his opinion as to the disease of which the party died, although he had never seen the deceased. So upon an indictment for murder the deceased's wounds being described, a surgeon may be called upon to give in evidence his opinion whether the deceased died in consequence thereof, or from natural causes, or whether the wounds were self-inflicted.'

"In view of all these authorities, it seems to me that the propriety which is now established of asking a medical man or other expert his opinion, assuming the facts given in evidence are within his knowledge, involves the proposition that he may remain in court and listen to the evidence, because it is not merely upon such facts, for instance, as are disclosed in the depositions, but all facts elicited in examination or cross-examination which tend to form material on which his opinion is based, and this cannot be satisfactorily dealt with unless the expert hears the evidence. There may well be matters to which neither side attach importance, which the expert on hearing them, may deem of great importance. Consequently, I think that, always subject to the discretion of the Judge but recollecting the established practice, a medical man or other expert should remain in court, and the value of his assistance in a technical matter to the jury and the Court would be much depreciated if he were excluded therefrom."

ARTIFICIAL SUNLIGHT IN INFANTILE PARALYSIS.

To the Editor of THE LANCET.

SIR,—May I mention in your columns the result of recent researches into the treatment of infantile paralysis in which I have used general radiation of the body by artificial sunlight, and local treatment of the affected muscles by red rays?

The observations which led to my using general radiation by artificial sunlight were as follows. In 1920 I began the study of artificial sunlight treatment at St. Thomas's Hospital. I chose as one of my groups of cases children suffering from rickets. This work I did in coöperation with Dr. R. C. Jewesbury. We found that about a month's treatment with artificial sunlight was enough to secure a virtually normal X ray picture of bones which had shown at the beginning of treatment a marked deficiency in calcification. I found at the beginning of their treatment these children were fretful. They did not like to be touched; they cried at the least thing; did not like having their clothes put on; slept badly; did not put on weight and, in short, appeared to me to be suffering from symptoms of acute neurasthenia. These symptoms were the first to clear up under the light treatment. They were rapidly transformed into happy, contented and easily managed children. This change was the first to appear; it came even more quickly than the bony recovery, and it appeared to me that the change was due to the rapid improvement of nutrition in the nerve centres under the action of light. I followed up the broad hint furnished by this observation by treating a series of children suffering from infantile paralysis at the Heritage Craft Schools, Chailey, with artificial radiation obtained from a mercury-vapour lamp used in conjunction with a group of lamps consisting of carbon filament in vacuo with a suitable reflector.

With regard to local treatment of the muscle by red rays, at Leysin Dr. Augustus Rollier showed me the wonderful improvement in muscular development that took place under the sun's rays, and he told me he thought this must be due to the action of the red or infra-red rays. The infra-red rays are absorbed and diffused by water, consequently the water in the tissues prevents the heat rays from penetrating them deeply. The red, on the other hand, are not interrupted by water, and it is easy to see how they penetrate the tissues by merely holding the hand in the path of a sun-beam entering a shady room when the red rays can be seen to penetrate the fingers easily. In order to secure the intense radiation of the paralysed limbs with red rays, I passed the rays from the carbon-filament lamps through red screens, so screening off much of the heat without cutting down the red rays. I could thus use a red light of much greater intensity than is possible without the red screen. This treatment was used in addition to the ordinary electrical treatment.

The results obtained were far in advance of anything I have seen in the course of a long experience in the treatment of such cases. They show a recovery of faradic and voluntary response in muscles that were so much atrophied as to give no electrical response at the beginning of the treatment, and in some cases the initial attack had taken place many years before the treatment began. I am submitting a detailed communication.—I am, Sir, yours faithfully,

G. MURRAY LEVICK.

Harley-street, W., March 16th, 1925.

STOVARSOL IN THE TREATMENT OF SYPHILIS.

To the Editor of THE LANCET.

SIR,—In your issue of March 7th reference is made to acetyloxyaminophenylarsinic acid, known as "190," or stovarsol, and to the protection it affords against syphilis when taken by the mouth soon after exposure to infection. Experiments have amply demonstrated that stovarsol will prevent development of primary lesions if administered by the mouth sufficiently early; it has also considerable value in the treatment of the disease when manifested. It is an active remedy in yaws, and is being used with great success in the treatment of amœbiasis. The product is supplied in tablets, and we shall be happy to furnish full information to any member of the medical profession.—We, are, Sir, yours faithfully,

MAY AND BAKER, LTD.

Battersea, London, S.W., March 20th, 1925.

VESALIUS, RONDELET, AND RABELAIS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Feb. 28th, p. 447, there is a leading article upon a lecture by Prof. R. Cruchet. Therein it is stated that Vesalius studied for several years at Montpellier where he had as his master Rondelet. There is no authority given for this statement, which is at variance with generally accepted facts. After taking an Arts course in Louvain, Vesalius went to Paris to study medicine. He was then 18 or 19 years old and he remained at Paris for three years (1533–36). It is known that he spent some months thereafter in Louvain, Brussels, and Venice. He ultimately reached Padua, where his name first appears in the University records against the date Saturday, Dec. 1st, 1537. In Italy he remained teaching till 1543, when his famous *De Humani Corporis Fabrica* was published. There is no indication that he ever visited Montpellier at any time. Rondelet he may have known since both were numbered amongst the students of Gunterius of Andernach in 1535. Vesalius, however, nowhere mentions his name. In any event Vesalius could not have been his pupil since Rondelet did not become Professor in Montpellier till 1545.

There is just as little ground for placing Rabelais among the students of Rondelet. The creator of Pantagruel received the degree of Bachelor at Montpellier on Nov. 1st, 1530, he then being 47 years old. Rondelet had been studying in Paris for some years, but returned to his native town—Montpellier—in 1529 and forthwith received his licence. Armed with this he immediately started the practice of medicine in a small town of Provence. His attempt was, however, a failure and after turning to the teaching of grammar for a livelihood he again returned to Paris to improve his knowledge of medicine. It was then he became a pupil of Gunterius. Rondelet has been very commonly identified—probably upon the similarity of name—with Rondibilis, but it is scarcely necessary to add that the identification is purely conjectural.

I am, Sir, yours faithfully,

Edinburgh, March 16th, 1925. G. MATHESON CULLEN.

THE INFECTIVE FILTRABLE VIRUSES.

To the Editor of THE LANCET.

SIR,—The annotation headed as above in THE LANCET of March 21st gives information on what at the present time is the most important of all questions in biology and pathology. Though the most subtly-conceived and delicate experimentation and the most careful observation must be applied to the discovery of some details, a practical understanding of the kind of organisms that have filtrable stages is unlikely to be acquired if commonplace facts and obvious results of the simplest experiments are generally ignored.

The constant association of many specific filtrable viruses with specific cell-inclusions, as seen, for example, in mosaic disease of plants, molluscum contagiosum, variola, &c., is too often forgotten. In molluscum the cell-inclusions, called molluscum corpuscles, have been known for 70 years at least, and the presence of a filtrable virus in molluscum is well established. Placed in water in the simple way that I have described¹ the corpuscles constantly show activities, which prove them to be protists related to synchytrians. Their nature thus revealed, their histological relations prove them to be the cause of the disease. The filtered virus has also been proved to be the cause of the disease; therefore the molluscum corpuscle and the filtrable virus are but different phases of the same protist.

Any conclusions that may be reached in ignorance of the above-mentioned facts concerning molluscum should be very closely scrutinised.

I am, Sir, yours faithfully,

London, March 21st, 1925. J. JACKSON CLARKE.

THE GOULSTONIAN LECTURES.

To the Editor of THE LANCET.

SIR,—Through an error of mine in transcription Reference 50 in the first of my Goulstonian Lectures in THE LANCET last week reads as follows:—"Boldyreff, W.: *Quart. Jour. Exp. Path.*, 1914, viii., 1." It should, of course, have been "*Quart. Jour. Exp. Phys.*, 1914, viii., 1."

In seeking to do justice to the more recent work on human gastric function I am afraid it may also appear that I have paid too little attention to the experiments of this distinguished physiologist. Prof. Boldyreff was the first to show on animals that gastric acidity is regulated by duodenal reflux and to point out that so-called hyperacidity must generally be due to defective neutralisation. Apparently he regarded positive forces in the duodenum (and not the behaviour of the pylorus, as my text might seem to suggest) as the important factor controlling alkaline regurgitation. I am, Sir, yours faithfully,

Wimpole-street, W., March 21st, 1925. J. A. RYLE.

¹ Protists and Disease, 1922.

TREATMENT OF SEPTICÆMIA.

At a combined meeting of the Sections of Surgery, Medicine, and Pathology of the Royal Society of Medicine held on March 24th, with Dr. Robert Hutchison (President of the Section of Medicine) in the chair, Sir Thomas Horder opened a discussion on the treatment of septicæmia. He said that his views on this subject differed little from those he held ten years ago. The nature of the infecting organism naturally bore on the treatment, and the two common cocci involved were the *Streptococcus pyogenes vel hemolyticus* and the *Staphylococcus aureus*. He classed the methods of treatment into three main groups: (1) General or non-specific measures, (2) bacteriotherapy, (3) chemo-therapy.

General or Non-specific Measures.—This group comprises: (a) Rest, both of the individual and of the region of the primary focus, if this was ascertainable. (b) Fresh air, to the extent permitted by the patient. (c) Sunlight. (d) Diet, which should be free, fluid at the height of the infection but containing many calories. (e) Reassurance, including the general attitude towards the patient and his complaint. (f) Hydrotherapy, about which there was considerable difference of opinion. In America this was more extensively used than in this country. (g) Elimination, with attention to bowels, skin, and kidneys. (h) Sleep. (i) Anodynes, among which he recommended opium, suggesting that we were too loth to use this drug nowadays. (j) Treatment at the site of infection, drainage, elevation, which gave much relief, heat, in the form of continuous baths or fomentations, and antiseptics. He was opposed to the use of very strong antiseptics which might interfere with the vitality of the tissues. (k) Intravenous infusion in acute cases. (l) Transfusion of whole blood, of which he had not had much experience. (m) Drugs, which were useful, but must not be relied on alone. He put first arsenic, preferably in the form of sodium cacodylate, one grain in one c.cm. of a saturated solution of nucleic acid or sodium nucleinate, given twice daily intramuscularly throughout the whole course of the disease. The smell of the breath showed when the patient was saturated with it. After that came opium and then such other drugs as quinine, strychnine, digitalis, and the hypnotics.

Bacteriotherapy.—This took the form of immune sera, bacteriological antigens, or combined methods. Sir Thomas Horder was accustomed to give an initial dose of not less than 50 c.cm. of univalent antistreptococcal serum intravenously on the first day, repeating it on the second, perhaps on the third day. By that time an autogenous vaccine could usually be prepared, the sensitised type being the most advantageous form, given in doses of 100 million the first time, 250 million on the third day, and 500 million on the fifth or sixth day. In "immunogen" an attempt had been made to get certain products of auto-digestion of the micro-organism as well as the endotoxin, and this substance was worth trying.

Chemotherapy.—This took the form of chlorine or coal-tar derivatives, metals, or colloidal metals. These had proved disappointing. In the staphylococcal form of the disease the infection was more pyæmic, giving more time, but having the disadvantage that no serum could be prepared. The treatment of chronic septicæmic processes such as ulcerative endocarditis was as disappointing to-day as ten years ago; the best line to take was that of using all possible non-specific methods, especially sunlight.

Prophylaxis.

Mr. R. P. Rowlands regarded prophylaxis as extremely important. It could be accomplished by taking every precaution against infection during operations, by prompt excision of contaminated

wounds, prompt removal of local sources of systemic infection such as acute appendices, perforated ulcers, acute infective osteomyelitis of long bones and anthrax lesions, by the careful opening of boils and carbuncles, and by the universal use of rubber gloves at operations and autopsies. When the disease was once established the physician, bacteriologist, hæmologist, and surgeon should collaborate and should seek constantly to find, remove, or treat the source of infection, which might be occult, such as dental abscesses, tonsillar or gall-bladder infections, pus hidden deep in the buttock, loin, liver, calf muscles, or pelvis. Whole blood transfusion seemed more helpful than immuno-transfusion, being quicker; it combated the anæmia and raised the immunity. Sunshine, feeding-up, and careful nursing were valuable accessories.

Functional Activity of Leucocytes.

Dr. L. Colebrook spoke of the work done by himself and his colleagues at St. Mary's Hospital in the attempt to find out where it was that the mechanism of defence broke down in these cases. The answer seemed to be that there was a diminution in the functional activity of the leucocytes, which might be increased in actual numbers, but had their function reduced to one-half or one-tenth of the normal. This phenomenon was met with in all infections, even the common cold, but was at its maximum in streptococcal septicæmia. This might not be the whole story but was a very large factor, and its computation gave a better idea of prognosis than any other method, with the possible exception of an actual microbic count. The treatment suggested by these results was to neutralise the toxins and kill off as large a number of microbes as possible. The process of active immunisation was not hopeful; the leucocytes were so injured that no response could be obtained from them by a vaccine. The body seemed to make little or no response to septicæmic infection. Passive immunisation by antisera seemed rather hopeless also. There was but slender evidence to show that any antiserum destroyed the bacteria or neutralised toxins, and sometimes the patient was made worse and in any case was liable to serum-sickness and discomfort. The use of immuno-transfusion seemed to be in borderline cases, where it was doubtful whether there were actually micro-organisms in the blood. It was customary to give the donor 1000 million staphylococci and wait three or four hours before transferring the serum. On the whole, the results were disappointing; in grave cases the patient was not saved. A better method of immunising donors was still being sought; the process was valuable but should not be relied on alone to save cases. In chemotherapy the conditions demanded of a drug were: (1) That it should not further diminish the activity of the patients' leucocytes or destroy other essential tissues; and (2) that the patient's blood should be shown to be bactericidal to the infecting microbe after its administration and to remain so for a sufficient period; or (3) that the blood after administration should be capable of neutralising the toxin that was destroying the leucocytes. None of the drugs mentioned fulfilled these conditions, but in the neosalvarsan group was a collection of substances which were satisfactory in this respect. In all cases there was an increase of a few thousands for some hours; the drugs seemed nearly specific to the *Streptococcus hemolyticus*.

Sir Almroth Wright expressed the opinion that the clinical line of approach to medical problems should be replaced by a more scientific attitude. He had classified it as the "saltus empiricus"; clinicians saw only the remote results and paid no attention to immediate results. Nothing would ever come out of clinical observation. Immuno-transfusion was not to be classed as a failure; it was only a limited method.

Mr. Zachary Cope said that all the pathology of the blood and tissues was not yet known; a great deal of the problem of immunity was still a shibboleth of "We believe, we think, we hope and we trust." There was as yet no answer to the question as to why

certain microbes selected certain tissues for their activity and were relatively harmless in others. He asked what was the function of the cellular tissue in the body in resisting septicæmia and what was the function of the epithelium in withstanding bacteria on its surface. In his opinion the clinician must continue to use his judgment and do what he could until more accurate knowledge of the selective activity of the tissues of the body was obtainable.

Dr. Hutchison spoke of the relief he had obtained from the immersion of a septic finger in a bath and the free use of port as a general means of maintaining strength.

Mr. Herbert Tilley recorded a personal experience of septicæmia, due to a prick through a glove. In an early stage he had obtained remarkable temporary relief from an injection of serum. In later stages the greatest relief had been given by free incision, immersion of the limb in hot baths, elevation and the administration of chloral and bromides as hypnotics. Morphine made him feel ill all next day. In the matter of scientific medicine, he pointed out that practice sometimes preceded scientific explanations; soldiers knew better than to bivouac in mosquito-haunted swamps years before the cause of malaria was worked out, and the shepherd on the hills had found, in his meal of bread, cheese, salt, an onion, and a bottle of beer, the perfect diet since acclaimed by physiologists.

Obituary.

MARY DARBY STURGE, M.D. LOND.,

PHYSICIAN TO THE BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.

WITH the recent death of Dr. Mary Sturge, a pioneer among women doctors in Birmingham, there passes one whose life was a record not only of devoted work in the service of medicine, but of continual and selfless striving in the wider field of social life for the betterment of humanity.

Miss Sturge was born in 1862 in Edgbaston, of Quaker parentage, her father being Wilson Sturge, former Mayor of Birmingham, who was a staunch adherent to the principles of the Society of Friends. She received her early general education at Edgbaston High School for Girls, and at the age of 18 she entered, with a few other women students, the Mason Science College of Birmingham University which had just opened. Six years later, in 1886, she passed the preliminary scientific examination of the London University, and entered the London School of Medicine for Women, her application to study at the medical school of Birmingham having been refused. In London Miss Sturge had a distinguished student career; she took honours in anatomy in the intermediate M.B. examination and honours in medicine in the final M.B., while she was awarded the Prideaux Scholarship for an original paper on clinical obstetrics. Her first appointment after graduation was as resident at the Clapham Maternity Hospital, and at the same time she acted as physician to the Dispensary for Women and Children. Between 1892 and 1895 she held successively the posts of resident at the North-Eastern Fever Hospital and as senior resident at the New (now Elizabeth Garrett Anderson) Hospital for Women. Having gained the M.D. Lond. in 1895, she took up general practice in Edgbaston, where the rest of her life was spent. From 1895 to 1905 she was attached to the Birmingham and Midland Hospital for Women as anaesthetist, and from 1905 till her resignation in 1924 she held the position of honorary physician on the hospital staff. Outside the work of her practice she was active in many things pertaining to medicine and to the general welfare of her fellows. In 1894 she delivered the inaugural address at the opening of the session at the London School of Medicine for Women, and during the years 1920 to 1922 she was the first pro-

vincial president of the Women's Medical Federation, an organisation which she had helped materially to build and in which she took the keenest interest. Her work in the cause of temperance, of which she was ever an enthusiastic advocate, was crowned by the publication in 1907 of "Alcohol and the Human Body," written with the collaboration of the late Sir Victor Horsley. Her great care for the well-being of children was further revealed in her constant insistence on the importance of sunlight and fresh air for healthy growth—at a time when neither of these were generally accepted as essentials for happiness. One of her recent enterprises was the founding of the Birmingham Taylor Memorial Home for Inoperable Cancer.

Miss Sturge was a fine physician and a great woman, with the soul and spirit of a pioneer, which won the respect of her colleagues and the love of her patients.

THE BATEMAN APPEAL.

As already explained in THE LANCET, it has been felt that material assistance ought to be offered to Dr. Bateman to meet the legal expenses of his recent successful appeal against conviction and to make good the deficiency in his professional income. Accordingly, the Bateman Fund has been opened and lists of contributions have appeared in recent issues. We have received additional contributions as follows:—

	£	s.	d.
Already received and acknowledged	379	3	0
Dr. G. H. Adam	..	..	5 0
Dr. A. L. Vaughan	..	..	5 0
Dr. Arthur J. McNair	..	..	3 0
Dr. F. C. Poynder	..	..	2 0
Dr. J. Stewart	..	..	2 0
Dr. W. H. Coupland	..	..	1 0
Dr. Hugh Lawson	..	..	1 0
Dr. H. W. Newton	..	..	1 0
Dr. T. J. T. Wilmot	..	..	1 0
Dr. F. C. Bottomley	..	..	1 0

Remittances should be forwarded to the Manager of THE LANCET, 423, Strand, W.C.2, and made payable to the "Bateman Fund Account."

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates passed in the subjects indicated:—

Surgery.—W. Bentley, Birmingham; N. E. Challenger, McGill; A. J. M. Davies and A. Kaplan, St. Mary's Hosp.; Y. N. Lal, Dundee; T. K. Natesan, London Hosp.; and F. T. Ridley, Birmingham.

Medicine.—A. H. Allam (Sect. II.), St. Mary's Hosp.; T. K. Natesan, London Hosp.; and F. T. Ridley, Birmingham.

Forensic Medicine.—E. H. Boodrie, St. Mary's Hosp.; M. R. Burke, St. George's Hosp.; B. Horwitz and T. McD. Kellough, Guy's Hosp.; A. Mishriky and C. M. Moody, St. Mary's Hosp.; C. C. Po, Guy's Hosp.; F. T. Ridley, Birmingham; and B. L. Steele, Univ. Coll. Hosp.

Midwifery.—I. H. Mackay, Sydney; K. V. Mead, St. Thomas's Hosp.; E. J. Newman, London Hosp.; F. T. Ridley, Birmingham; and R. J. Rutherford, Durham.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: A. H. Allam, W. Bentley, N. E. Challenger, A. J. M. Davies, Y. N. Lal, A. Mishriky, T. K. Natesan, C. C. Po, and F. T. Ridley.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council of the College held on March 12th licences to practise dentistry were conferred upon 82 candidates. The following are the names and schools of the successful candidates:—

P. Adelson, Royal Dental; H. R. Allen, Guy's; S. G. Allen, London; W. J. Badenhorst and W. P. Beresford, Guy's; R. F. Beveridge and H. C. Beyers, Royal Dental; A. Caldwell, Manchester; F. H. Chapple, Guy's; H. I. Clapperton, H. Clausen, and W. D. E. Clayton, Royal Dental; O. E. Clements, Univ. Coll.; E. J. Clothier, Guy's; A. M. Cohen, M. Cohn, and E. D. Collins, Royal Dental; L. Cowlishaw, Guy's; A. T. Craig, Univ. Coll.; J. S. Crapper, Guy's;

F. T. Cullen, Royal Dental; Marie J. V. R. de Plamas, London; D. S. Dixon and W. G. Duncombe, Royal Dental; J. W. Finemore, G. W. Gathergood, H. A. Gillett, G. E. Glazebrook, G. M. Glennie, N. Goldthorpe, and E. C. Grant, Guy's; S. Grantham-Hill, London; W. E. Herbert, Guy's; J. Hovsha, Royal Dental; H. Howard, Manchester; S. R. Howeroff and D. A. James, Guy's; T. P. Kapadia and C. H. Kennard, Royal Dental; J. C. Laight, Univ. Coll.; H. C. Lawrence, Guy's; C. H. McGivern, Royal Dental; H. C. L. Maister, Guy's; F. G. Mallett, Royal Dental; W. R. Mason, Birmingham; Adeline M. Matland, Royal Dental; G. Meadows, Bristol; V. H. L. Meyers, Royal Dental; A. D. Miller, Guy's; G. Miron, Univ. Coll.; C. I. T. Morgan, Bristol; L. A. Moules, S. N. Muir, and J. H. Mynhardt, Royal Dental; J. G. Nelson, Guy's; Olive Nicholls and S. H. Oomrigar, Royal Dental; R. H. N. Osmond, London; Winifred N. Pilcher, D. D. Pochin, and J. J. Reader, Royal Dental; E. B. Rees, Guy's; W. E. Revill and A. L. Robison, London; L. F. O. Seymour, Guy's; F. W. Sievers and C. H. Soutter, Royal Dental; L. A. Steel, Guy's; Ella M. Storey, Univ. Coll.; Amelia Tobias and H. J. Toerien, Royal Dental; F. H. B. Tofts and S. Thomson, Guy's; V. A. Vasey, Manchester; do W. Vorster, Guy's; W. G. Webster, Birmingham; J. F. Wege, Guy's; T. H. Wignall, Liverpool; E. C. Wilkerson, London; G. S. Williams, Univ. Coll.; and W. R. Williams, London.

Diplomas of M.R.C.S. were conferred upon the following, who have passed the requisite examinations and have now complied with the by-laws.

Victor Alexander Edge, Madras and London Hosp.; and Gladys Evelyn McCabe, Royal Free and St. Mary's Hosps.

UNIVERSITY OF LONDON.—A Keddey Fletcher-Warr studentship of the value of £200 a year for three years has been awarded to Douglas Creese Harrison, B.Sc. (King's College), for research in biochemistry.

UNIVERSITY OF MANCHESTER.—At recent examinations the following candidates were successful:—

DIPLOMA IN PUBLIC HEALTH.

Part II.—Hilda Pratt.

Part I.—E. R. Gilmore, Bridget Lineham, and A. C. Newman.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

Part I.—W. G. Thomson.

DIPLOMA IN VETERINARY STATE MEDICINE.

Parts I and II.—R. C. Locke and Reginald Lovell.

UNIVERSITY OF LIVERPOOL.—Honorary degrees will be conferred at a special congregation on June 5th on, amongst others, the following distinguished members of the medical profession:—LL.D.: Sir Dyce Duckworth, Sir Robert Jones, and Sir Henry Hadow (Vice-Chancellor of the University of Sheffield); D.Sc.: Principal Sir J. C. Irvine (Vice-Chancellor of the University of St. Andrews).

ROYAL NAVY MEDICAL CLUB.—The annual dinner will take place this year at the Trocadero Restaurant, Piccadilly Circus, W. 1, on Thursday, April 16th, at 7.30 for 8 P.M. Members who wish to be present are asked to inform the Hon. Secretary, Royal Navy Medical Club, 68, Victoria-street, London, S.W. 1, not later than seven clear days before that date.

BALNEOLOGICAL CONGRESS.—The Fortieth Congress of Balneology organised by the Balneologische Gesellschaft, Berlin, will be held from April 3rd to 8th in Karlsbad, Marienbad, and Franzensbad. Prof. Dietrich will preside. Full information may be obtained from the General Secretary, Dr. Hirsch, 16, Franzhofer-strasse, Charlottenburg, near Berlin, Germany.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—It is proposed to resume the discussion on Post-Graduate Study in London at the house of the Royal Society of Medicine on Wednesday, April 8th, at 6 P.M. Sir Arbuthnot Lane will again preside, and it is hoped that many members of the medical profession will attend and give their views.—Other lectures are announced in the Medical Diary.—During April three special courses will be held, each of two weeks' duration; an intensive course in Medicine, Surgery, and the specialties at the Hampstead General Hospital; during both weeks there will be a daily morning and afternoon session, including clinical demonstrations, ward clinics, and out-patient work.—A course in Diseases of Children at the Queen's Hospital, Hackney-road, E.; work will be carried on in the wards, out-patient and special departments.—The other course is on Proctology at St. Mark's Hospital for Diseases of the Rectum, at which will be given clinical lectures with operations and demonstrations of the methods pertaining to rectal diseases. Copies of the syllabus of the foregoing courses may be obtained on application to the Secretary to the Fellowship of Medicine at 1, Wimpole-street, London, W. 1. The following special courses will take place in May: Dermatology, Diseases of Infants, Nose, Throat, and Ear, and Psychological Medicine.

CREMATION SOCIETY OF ENGLAND.—The annual meeting of subscribers will be held in the Adam Hall, at 12, Stratford-place, London, W. 1, on Wednesday, April 8th, at 3 P.M.

AUGUSTUS AND ALICE WALLER MEMORIAL.—£2000 have been subscribed for the memorial to Dr. and Mrs. Waller. The money has been invested by the Council of the Royal Free Hospital School of Medicine for Women, London, and the interest will be used for scientific research at that school. For a Waller research room at St. Mary's Hospital so far £105 have been subscribed.

ROYAL DENTAL HOSPITAL.—The annual general meeting of governors of this institution was held on March 19th at the hospital, Leicester-square, London, W.C., when the Chairman, Sir Fisher Dilke, presided over a large body of supporters, and made a wise speech. It was trying, he said, to an audience to be supposed to be interested in such deep truths as that the number of patients who were treated for plastic fillings was 17 odd thousands, or that a dozen hæmoglobin tests were safely applied, and he proposed to refer his hearers for such information to the annual report. But he enlarged a little on the double task of the hospital in providing treatment for the teeth of the poor of London, and of educating its patients, and London generally, until they realised the vital need of healthy teeth as companions to a healthy body and mind; and he called particular attention to the opening of the greatly enlarged children's department and X ray room. For some time those responsible for the management of the hospital, he said, had felt that the children should be attended in a department of their own where special care could be given to them—this had been accomplished by a reorganisation of departments and to a certain extent by re-building. A considerable sum of money had been spent on this work, and he acknowledged a most generous contribution of over £600 through the action of Sir Oswald Stoll in placing the Alhambra Theatre at the disposal of the hospital for a concert. The X ray department had also been greatly enlarged, as it was becoming more and more indispensable as a means of diagnosing obscure dental troubles, from which so many of the patients suffered. "But the hospital has," he said, "outstanding a large amount of the mortgage on our building, and banker's orders paying even the most modest sums into our account annually are what we daily pray for, while welcoming the magnificent gift which all hospital committees dream of." He closed by asking the meeting to voice their sincere thanks for the help and encouragement received from the honorary staff.

MENTAL AFTER-CARE ASSOCIATION.—The annual meeting of this Association was held at the Clothworkers' Hall, London, on March 18th, Sir Charles Wakefield, the President, presiding. The speakers included Sir Frederick Willis, chairman of the Board of Control, Dr. H. Wolseley-Lewis, medical superintendent of Maidstone Mental Hospital, and Mr. Lionel Faudel Phillips, hon. treasurer of Bridewell and Bethlem Royal Hospitals, and various members of the Council. There was a large attendance and much interest was evinced in the proceedings. Dr. Rayner, chairman of the Association, in moving the adoption of the report, referred to the very large increase in the number of cases dealt with in the previous year and the greater public support that was needed in order to enable the Association to meet the ever-growing demands on its resources. He announced with great pleasure among other donations the gift of £500 from Sir Charles Wakefield. Sir Maurice Craig, treasurer of the Association, drew attention to the fact that the expenditure last year exceeded the receipts by some £1100, and also to the fact that one-third of the total receipts last year were contributions from patients and their friends, in itself a wonderful tribute to the way in which the work is appreciated by those for whom it is intended. Other speakers were unanimous in their approval of the way in which the work was carried out. Sir Frederick Willis said that he sincerely hoped in time some means would be devised whereby the Association could be lightened of some of its financial worries while increasing the scope of its work to extend all over the country. Dr. Wolseley-Lewis pointed out that the extension of the work with regard to the arrangements for visiting the homes of patients before discharge and reporting to the medical superintendents, and keeping in touch after discharge was to his mind an enormous help to the medical superintendents and visiting committees, and enabled many patients to be discharged more quickly. He urged that more help should be raised in the hospitals by musical services, offertories, and collecting boxes. The meeting closed with a vote of thanks to Sir Charles Wakefield for presiding and for his generous gift, and to the Clothworkers for their hospitality in entertaining the large number present. Other donations included gifts of £10 from the Clothworkers' Company, from Mr. L. H. Bolton, and Mr. L. G. Foster.

ON the promotion of Sir A. Symonds, K.C.B., Second Secretary, to be Secretary to the Board of Education, the Minister of Health has approved the appointment of Mr. E. R. Forber, C.B., C.B.E., to be Deputy Secretary to the Ministry, and Mr. L. G. Brock, C.B., and Mr. I. G. Gibbon, C.B.E., to be Principal Assistant Secretaries.

A NEW KENSINGTON HOSPITAL.—The Kensington, Fulham, and Chelsea General Hospital is the only institution of its kind amid a population of half a million, and its 19 beds are obviously inadequate. It has, therefore, been decided to rebuild it from designs by Sir Aston Webb, on a 112-bed basis, at a cost of £100,000. The scheme has the financial support of King Edward's Fund.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.—A course in parasitology will be held at the Tropical Division of the school from April 27th to June 25th. The fee for the course is £2 2s. Lectures will be given on entomology by Colonel A. Alcock, on helminthology by Prof. R. T. Leiper, and on protozoology by Dr. J. G. Thomson. The course is primarily intended for students taking the first part of the D.P.H., but there may be room for other students. Further information may be obtained from the Secretary of the School, at the temporary offices, Institute of Historical Research, Malet-street, London, W.C. 1.

MANCHESTER ROYAL INFIRMARY.—The post-graduate lectures and demonstrations on medical, surgical, and special subjects, given by the honorary staff, were resumed on March 3rd, and will be held each week (with the exception of Tuesday, April 14th) till May 26th. On Fridays clinical cases will be shown in the wards. These demonstrations will be continued (with the exceptions of April 10th and 17th) till Friday, May 22nd. All the lectures and demonstrations will commence at 4.15 P.M. There will be no fee.

LIVERPOOL: NEW OPERATING DEPARTMENT AT MILL ROAD INFIRMARY.—On Tuesday, March 24th, in the presence of a large assembly, a new operating department at Mill Road Infirmary was opened by Mr. John Ellis, chairman of the infirmary. The site chosen is on the ground floor in the north-east courtyard between two ward-blocks. The scheme suggested by Dr. R. T. Bailey, medical superintendent, and Mr. O. Herbert Williams, visiting surgeon, has been very ably planned by Mr. E. B. Bailey, M.S.A., F.S.I., the architect, and carried out under his direction. There are two entrance halls. From the one, which leads from the surgical wards, access is had to a dressing-sterilisation room with an adjoining store-room, a robing room for the surgeon and assistants, with a shower-bath and lavatory. Off the other hall is a robing room for nurses. These halls lead to a large octagonal court, lit by a dome in which are doors leading into a cystoscopy room, a laryngological operating-room, two anaesthetic rooms, two operating theatres, with an instrument sterilisation room between them. Each theatre is 25 ft. long by 16 ft. wide, and is lit by a north light. The guardians of the West Derby Union are to be congratulated on building this splendidly equipped operating department, which will be of great benefit to the sick of Liverpool. Messrs. Brown and Backhouse, of Liverpool, were the contractors for the work. On the same day the new X ray department and electro-therapeutic department were opened.

CHELSEA CLINICAL SOCIETY.—The fifth meeting of the present session of this society was held at St. George's Hospital on March 17th, Dr. Gordon Lane, the President, in the chair. Dr. Leonard Williams read an entertaining address on the diseases of old age. Constipation and errors in diet, in the way chiefly of excess, were, he said, in great part responsible for senile troubles. The dentist was the aide-de-camp of the cook, and dealing with the control exercised over the body functions by the ductless glands the adrenal was considered to be at fault in many cases of disease in the old man and woman. Mr. Kenneth Walker thought that in some cases ligation of the vas deferens was a useful operation, but in his opinion grafting in the testicle did a great deal of good. Mr. Ivor Back confirmed this view from the experience of about 30 per cent. of his cases, though in a great many the operation of putting a graft in the testicle had not fulfilled expectations. Mr. Back gave an interesting account of testicular grafting which he had performed in a valuable boar, the result being that the boar which had shown no desire for female society reversed his proclivities but apparently had no procreative power. Mr. Ralph Thompson gave some of his experiences of dissections of the ductless glands. The general opinion of the speakers was that when a graft was put into some organ, the result was certainly not immediately shown.

The next meeting will be held at St. George's Hospital on April 14th, when cases and specimens of clinical and pathological interest will be exhibited.

Parliamentary Intelligence.

HOUSE OF LORDS.

TUESDAY, MARCH 17TH.

Therapeutic Substances Bill.

THE House went into Committee on the Therapeutic Substances Bill.

The Marquess of SALISBURY (Lord Privy Seal) stated that the Government had considered the point raised by Viscount Haldane on the Second Reading in regard to permission being given to men of science to obtain therapeutic substances for use in research work without a licence. It was proposed to issue special licences to individuals or institutions enabling them to import at will parcels of these substances for research purposes. The information that A. B., being a scientific man of eminence, or C. D., being a scientific institution, had received such licences would be conveyed to the Customs authorities and would be quite sufficient to obtain the necessary permission to import.

The amendment was agreed to.

THURSDAY, MARCH 19TH.

The Therapeutic Substances Bill was read a third time and passed.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 18TH.

Naval Ratings Discharged Medically Unfit.

MR. HORE-BELISHA asked the First Lord of the Admiralty whether he was prepared to consider the suggestion that all ratings discharged from the Royal Navy medically unfit for further service, for reasons beyond their own control, be given a pension at the basic rate in respect of the length of their service, particularly in view of the fact that their careers had been ruined and that their wage-earning capacity had been depreciated.—MR. DAVIDSON (Parliamentary Secretary to the Admiralty) replied: As the present scales and conditions of pension for disability were determined after very careful consideration, I regret that I am unable to adopt the hon. and gallant Member's suggestion.

Invalided Naval Ratings.

MR. GIBBINS asked the First Lord of the Admiralty the number of lower ratings who were invalided from the naval forces during the year 1924-25; and the amount of compensation paid in these cases.—MR. DAVIDSON replied: Approximately 1200 men were invalided from the Royal Navy during the period from April 1st, 1924, to Feb. 28th, 1925. Of these 294 qualified for pensions at an average rate of £37 per annum, 850 qualified for gratuities only, at the average rate of £10. The remainder had less than a year's service and were ineligible for the grant of compensation.

Isolation Hospital in Parts of Lindsey.

Captain CROOKSHANK asked the Minister of Health whether the cost of erecting an isolation hospital for the treatment of infectious diseases in the Parts of Lindsey, as proposed, would have to be recovered by means of a special county levy over the whole area served by such a hospital, and that the cost of maintenance and treatment of patients would have to be recovered in the same way; and whether he proposed to introduce legislation this session with a view to removing this hardship which arose under the existing Public Health Acts.—MR. NEVILLE CHAMBERLAIN replied: The answer to the first part of the question is in the affirmative. As regards the second part, I am anxious to introduce legislation for the amendment of the Public Health Acts in this and other respects as soon as opportunity offers, but I cannot at present say whether this will be possible during the present session.

Health Conditions on British Ships.

Sir ROBERT HUTCHISON asked the Secretary of State for Foreign Affairs whether the British Government recognised the right of American consuls in the United Kingdom to withhold from British vessels clean bills of health on grounds other than those of the sanitary or health conditions of British ports or of the vessels or her crew; and whether an American consul was justified under any treaty or agreement with the United States of America in refusing to issue a bill of health from Glasgow to Manila on the ground that he disapproved of the nature of part of a cargo which was not illegal in either Britain or the Philippines.—Sir BURTON CHADWICK (Parliamentary Secretary to the Board of Trade) replied: There is no treaty or agreement between this country and the United States regulating the issue of bills of

health by the officers of the one country in ports of the other, and the issue of bills of health is governed by instructions given by the respective Governments. Neither Government is called upon to recognise the instructions given by the other.

National Health Insurance Payments.

Mr. SMEDLEY CROOKE asked the Minister of Health the amount spent each year since the passing of the National Health Insurance Act on medical service (doctors, medical supplies, medicine, &c.) and maternity benefit, respectively. —Mr. NEVILLE CHAMBERLAIN replied: The following statement gives the approximate amount spent in England and Wales in each year since the passing of the National Insurance Act, 1911, to the end of the year 1923 on the respective services specified in the question.

Year.	Payments of medical benefit.			Payments of maternity benefit.
	Medical service (doctors).*	Medical supplies (medicines, &c.).	Total.	
	£	£	£	£
1913	2,860,000	736,000	3,596,000	1,077,000
1914	4,140,000	1,051,000	5,191,000	1,206,000
1915	3,388,000	866,000	4,254,000	1,120,000
1916	3,699,000	956,000	4,655,000	1,079,000
1917	3,520,000	940,000	4,460,000	919,000
1918	4,115,000	1,041,000	5,156,000	882,000
1919	4,927,000	1,092,000	6,019,000	1,042,000
1920	7,413,000	1,543,000	8,956,000	1,695,000
1921	7,926,000	1,468,000	9,394,000	1,747,000
1922	6,961,000	1,488,000	8,449,000	1,606,000
1923	6,681,000	1,509,000	8,190,000	1,526,000

* Including payments to doctors in respect of the domiciliary treatment of persons suffering from tuberculosis.

Mr. SMEDLEY CROOKE asked the Minister of Health the number of sick and accident cases relieved each year since the passing of the National Health Insurance Act; the number of women relieved each year; the number of men relieved each year; the total number of weeks of relief; and the total number of insured persons each year. —Mr. NEVILLE CHAMBERLAIN replied: In the year 1923 there were approximately 13,317,900 insured persons in England and Wales, of whom 8,992,100 were men and 4,325,800 were women; and in that year the total payments of sickness and disablement benefits amounted to a sum of £11,533,400, of which £7,677,500 was paid to men and £3,855,900 was paid to women. A table giving for England the total number of insured persons, the receipts and expenditure on benefits for each of the last ten years is given on pp. 166 and 167 of the Fifth Annual Report of the Ministry of Health, Cmd. 2218 (1924). It is not possible to give the number of cases assisted in a year or the total number of weeks of sickness as no occasion has arisen for requiring approved societies to keep such statistics, and the necessary data are, therefore, not available.

Dismissal of Plymouth Medical Officer.

Mr. HORE-BELISHA asked the Minister of Health whether his department had received from the Plymouth Town Council a report of the proceedings culminating in the dismissal of Dr. Bushnell; whether he had approved this dismissal; and, if so, whether he would give the doctor an opportunity of having the charges against him specified in order that he might refute them. —Sir KINGSLEY WOOD replied: The answer to the first part of the question is in the negative. As regards the second part, my right hon. friend's approval is not required to the determination by the Town Council of their contract with Dr. Bushnell, and the last part of the question, therefore, does not arise.

THURSDAY, MARCH 19TH.

Appeals against Final Pension Awards.

Lieut.-Colonel ACLAND-TROYTE asked the Minister of Pensions whether he would consider the possibility of allowing men who were granted a final award for a disability assessed as under 20 per cent. to appeal within 12 months of the termination of the pension award instead of within 12 months of the grant of the award; and whether he would make this right retrospective in all cases of disability below 20 per cent. in which appeals had not already been lodged. —Lieut.-Colonel G. F. STANLEY (Parliamentary Secretary to the Ministry of Pensions) replied: Having regard to the provisions of Section 4 of the War Pension Act, 1921, the suggestion made in this question could not be carried out without legislation. In any event, however, my right hon. friend could not, in fairness to the general body of officers and men to whom final awards have been made, give an extended period of appeal to one class alone. My right hon.

friend would point out that the right of appeal is freely exercised in the class of case referred to, since, up to the present date, appeal has been made by slightly more than one out of every four cases in which a final award of this class has been notified.

Sick Benefit Regulations.

Mr. REID asked the Minister of Health whether, in the forthcoming comprehensive insurance scheme, he would consider the desirability of including a provision whereby those persons who, under the present regulations, were not entitled to claim any sick benefit, after a period of residence abroad exceeding one year, until the intervening contributions had been made up, or a further 104 contributions paid, might have imputed to them the benefit of those contributions made to the time of their leaving this country. —Mr. NEVILLE CHAMBERLAIN replied: Under the existing health insurance scheme an insured person who goes abroad for more than a year is treated, on his resuming employment in this country, in the same way as any other person entering insurance, and accordingly becomes entitled to sickness benefit, at a reduced rate after payment of 26 and full sickness benefit after payment of 104 weekly contributions following his return. I see great difficulties in the way of the adoption of the hon. Member's suggestion, but I am sending it to the Royal Commission on National Health Insurance for their consideration.

Industrial Smoke and Public Health.

Mr. ROBERT YOUNG asked the Minister of Health whether he was aware that about 70 per cent. of air pollution was the result of smoke from industrial chimneys; whether his department had taken any steps to investigate the problem of smoke prevention by the use of smoke-filtering apparatus and with what result; and whether he would inquire what had been done by way of experiment by the corporations of our larger cities. —Captain REID asked the Minister of Health whether, in view of the fact that 66 per cent. of the air pollution was due to smoke from industrial chimneys and that such air pollution was known to be injurious to health, any legislation was contemplated which would make the use of smoke-filters in factories compulsory. —Mr. NEVILLE CHAMBERLAIN replied: For the country generally, the proportions of industrial smoke stated by the right hon. Members appear to be much too high. I hope to introduce a Bill on the subject next session. I have no special information about smoke-filters, but if the hon. Members have any device in mind, I shall be pleased to receive particulars from them.

Housing Schemes under 1923 and 1924 Acts.

Captain T. J. O'CONNOR asked the Minister of Health the number of public authorities who, during the 12 months ended Feb. 28th, 1925, adopted the 1923 Housing Act and the 1924 Housing Act, respectively; and the number of houses for which permission had been given by the Minister to public authorities under each Act during this period. —Mr. NEVILLE CHAMBERLAIN replied: On Feb. 25th, 1925, the total number of authorities who had received approval to housing schemes under the Housing Act, 1923, was 1411 and these schemes provided for 184,202 houses. Proposals covering 73,056 houses were approved under the Act of 1923 in the year ended Feb. 25th, 1925, and 334 local authorities first adopted schemes under the Act in that period. Approval was given within the same period under the Housing (Financial Provisions) Act, 1924, to schemes of 311 local authorities covering 31,900 houses.

FRIDAY, MARCH 20TH.

Public Health Bill.

Mr. WOMERSLEY, in moving the Second Reading of the Public Health Bill, said he had served for a long time on a local authority and he knew the benefit that would be derived by local councils if this measure became law. The primary object of the Bill was to collect into one Act and make available for the whole country provisions which Parliament had already inserted in a great number of local Acts which had been privately promoted. It consolidated and brought up to date all the Acts connected with the public health. The Bill dealt with questions of principle which had already been decided by the House, and if there were any amendments to it he suggested they might be dealt with on the Committee stage. The measure was supported by municipal authorities throughout the country and had been wanted for a considerable time.

Mr. TAYLOR seconded.

Lieut.-Colonel FREMANTLE said he was glad to support the Bill from the point of view of his special experience as a county medical officer of health. It was largely a jumble of measures which had proved useful in one or other of the localities where they had been tried. There were two or three points which would have to be considered in Committee. Clause 59 defined "a dangerous infectious disease"

as a disease named in Section (6) of the Act of 1889. Unfortunately a great many unpleasant and dangerous diseases had been discovered since 1889. Under Sub-section (2) of Clause 59 the Minister of Health might by Order declare any other infectious disease to be a dangerous infectious disease for one particular area or generally or temporarily or permanently, and this would apply to diseases not named in the Act of 1889, as, for example, cerebro-spinal meningitis; it would also include tuberculosis and other diseases—in fact, anything which the Minister thought necessary. That allowed a very large amount of latitude and adaptability in the application of the Act. Since the great Act was passed by Disraeli in 1875 there had been a constant succession of Public Health Acts, and it was almost impossible for anyone who had not made a professional study of public health law and administration to know his way through the different charters of the last 50 years. He hoped that they would have a promise from the Government of a consolidating Public Health Bill within the next year or two, and that the House would agree to give this Bill a second reading unanimously.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) said that so far as his Department was concerned they welcomed this Bill and would be glad to see it secure a second reading. Naturally they would desire to examine the measure again in Committee, but subject to that the Government would be glad to afford it what facilities might ultimately be found necessary so that it might speedily reach the statute book. The Government were very anxious to bring forward a consolidating Bill. But they could not do so at present and this Bill was a necessary preliminary to any consolidating Bill. Directly this measure was passed the Government proposed to introduce another measure amending the Public Health Acts which experience had shown to be necessary. A Bill for this purpose was well advanced and would have been introduced this session, but the Association of Municipal Corporations was anxious that the Bill which the House was discussing that afternoon should be promoted as soon as possible. Two separate Public Health Bills could not be dealt with in the same session, and the Government therefore decided to defer the introduction of their Bill until the session of 1926.

The Bill was read a second time unanimously.

MONDAY, MARCH 23RD.

Indian Medical Service.

Major-General Sir RICHARD LUCE asked the Under Secretary of State for India the present strength of officers in the Indian Medical Service; how many of these were of European birth; and how many recruits, European and Indian, respectively, had been obtained for permanent service during the past 12 months and how many for short service.—Earl WINTERTON replied: The figures at the present time, as nearly as I can ascertain them, are: permanent officers 532 British, 142 Indians; temporary officers 148 Indians. In the last 12 months 14 British officers have been appointed to permanent commissions with the option of retiring with gratuities after five years' service. I am not aware how many Indians have been appointed in India to temporary commissions during that period. A number of Indians not exceeding ten have recently been or are about to be appointed to permanent commissions.

Local Authorities and Slum Properties.

Viscountess ASTOR asked the Minister of Health in how many cases objections to notices served by local authorities upon the owners of insanitary property, with a view to houses being put into order, had been raised on appeal to his Department; and how many of these appeals had been rejected.—Sir KINGSLEY WOOD replied: During the year ended Dec. 31st, 1923 (the last year for which figures are available), notices requiring repairs, &c., under the Housing Acts were served in respect of 25,277 houses. During this year 37 appeals were received by the Department, 5 appeals were formally dismissed, 3 allowed, and 4 allowed in part. The remainder were not proceeded with.

Test of New Remedy for Foot-and-Mouth Disease.

Sir JAMES REMNANT asked the Minister of Agriculture where it was proposed to build the isolated experimental station at which the official test of Dr. John Shaw's remedy for and prevention of foot-and-mouth disease was to be made; if the building had been started; from whom the doses with which the test was to be made were being obtained; and whether he had decided that Dr. John Shaw should be present and carry out the test when it was made.—Mr. WOOD replied: It is not proposed to build a new experimental station for the purpose of testing Dr. Shaw's remedy. The premises at Pirbright formerly used by the Ministry as a cattle-testing station, which are being adapted for use by the scientific committee on foot-and-mouth disease,

will be utilised for the purpose. No doses of the remedy have yet been obtained, but I presume that Dr. Shaw will be prepared to supply them when required. It is not legally possible for Dr. Shaw personally to carry out the tests without a licence granted by the Home Secretary under the Cruelty to Animals Act, 1876, which I am advised he does not hold, but I propose to invite him to concur in the suggested scheme of experiments, and to be present during their conduct by the responsible officers of the Ministry's Veterinary Staff.

TUESDAY, MARCH 24TH.

R.A.M.C. Officers' Pensions.

Maj.-Gen. Sir RICHARD LUCE asked the Secretary of State for War if he was aware that an officer in the Royal Army Medical Corps had recently retired, after 20 years' service, with a pension of £328 per annum, and that this sum was £37 below the sum he understood he would receive, after 20 years' service, when he joined the corps; and if he would take steps to secure that no officer who joined the corps before the Warrant of 1919 came into force would in future be retired on a lower pension than he would have received under conditions existing when he joined the corps.—Sir L. WORTHINGTON-EVANS replied: The fact referred to by the hon. and gallant Member is due to the joint effect, on this individual case, of the rule that service on the West Coast counts double towards the 20 years required for voluntary retirement and of the introduction in 1919 of a rank element into the calculation of retired pay. I am, however, looking further into the position.

Sir RICHARD LUCE also asked the Secretary of State for War whether he was aware that a major, Royal Army Medical Corps, retiring after 20 years' service, only received an increase by the 1919 Warrant of £31 to his previous pension of £365 and that, by the reduction of 5½ per cent. on the increased pension of £396, he had had the increase reduced not by 27½ per cent. but by nearly 67 per cent.; and if he would take steps to secure that these officers did not in future have their pensions reduced by a larger amount than 27½ per cent. of the increase granted in 1919.—Sir L. WORTHINGTON-EVANS replied: My hon. and gallant friend's question is, I think, based on a misapprehension. The revision due to the fall in the cost of living, which was made from July 1st last, applied to the 1919 rate of retired pay itself and not to the difference between the rates under the 1914 and 1919 Warrants. A reduction of 5½ per cent. was therefore applied correctly to the 1919 Warrant rate of £396 per annum in the instance quoted.

Physical Defects in Army Recruits.

Mr. GILLET asked the Secretary of State for War what number of the 49,245 men who were rejected last year as recruits to the Army were refused on the ground of defective eyesight and what number on account of defective teeth.—Sir L. WORTHINGTON-EVANS replied: The information required is only available in the case of the 20,742 men who were rejected by medical officers on primary medical examination and after attestation. Of these, 1743 were rejected for defective vision and 2062 for defective teeth.

WORTHING HOSPITAL.—The governors of Worthing Hospital, at the annual meeting on Feb. 27th, gave consent to plans for the rebuilding of the administrative department, provision for the accommodation of the domestic staff, and the reorganisation of the heating and hot-water systems, the total sum involved being £8000. Authority was given the committee to pay such balance out of capital as might be necessary to carry out the work. Mr. H. R. P. Wyatt, J.P., the President, announced the gift of £500 from a generous friend towards the building fund, and the same generous friend had promised another like sum if the residents would do their share.

THE LATE DR. FRÉDÉRIC MORIN.—Dr. Frédéric Morin, President of the Station Climatérique de Leysin, died recently at Leysin, Switzerland, in his seventy-third year. Dr. Morin was born at Yverdon, and studied medicine in Lausanne and Berne, qualifying in 1877. He practised first at Colombier on the Lake of Neuchâtel. In 1890 he became, with Dr. Louis Secretan, the chief promoter of the Société de la Station Climatérique de Leysin, a body founded with the object of creating at Leysin a resort for the cure of tuberculosis. Later he became medical adviser of the Sanatorium des Enfants and of the Sanatorium Populaire at Leysin. Further, he was one of the founders of the International Union against Tuberculosis, of which he was later elected President. At several meetings of this Union he contributed valuable papers on the sun treatment of tuberculous diseases. Dr. Morin presided over the congress of the Union, which was held at Lausanne last year.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY, Burlington House, Piccadilly, W.
THURSDAY, April 2nd.—4.30 P.M. *Papers to be read:*
Prof. H. E. Armstrong: Studies on Enzyme Action, XXIII. The Oxidase Effect and the Phenomena of Oxidation in General. Carbonic Oxide. N. K. Adam and G. Jessop: An Explanation of the so-called Interaction Phenomenon between Solutions and the Molecular Significance of Negative Surface Tension. (Communicated by Sir William Hardy, Sec. R.S.)—*Papers to be read in title only:* Jane Sands, M.D.: Investigation of Oxidation in the Blood of Earthworms. (Communicated by J. Barcroft.) R. Snow: Conduction of Excitation in the Leaf of Mimosa Spegazzinii. (Communicated by Dr. A. H. Church.) Dorothy Adams: Investigations on the Crystalline Lens. (Communicated by the Glassworkers' Cataract Committee.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W. MEETINGS OF SECTIONS.

Tuesday, March 31st.

MEETING OF THE SOCIETY: at 5.30 P.M.

Special Discussion on
Endocrine Therapy.

Opening Speakers:

Dr. W. Langdon Brown, Prof. Swale Vincent, Mr. Leslie Pugh, Dr. H. Gardiner-Hill, Mr. Kenneth Walker.

Other Speakers:

Dr. Leonard Williams, Dr. H. Crichton Miller, Mr. J. E. R. McDonagh, Dr. M. B. Ray, &c.

(The Meeting, if necessary, can be adjourned at 7 P.M., and resumed at 8.30 P.M.)

Wednesday, April 1st.

SURGERY: at 8.30 P.M.

Paper: (illustrated by diagrams, microscope slides, and cinema films) on

Some Results of the Experimental Anastomosis of Certain Nerves with Neighbouring Nerves, by Sir Charles Ballance, Mr. Lionel Colledge, and Mr. Lionel Bailey.

LARYNGOLOGY } Members of these Sections are specially
MEDICINE } invited to attend this meeting.
NEUROLOGY }

Friday, April 3rd.

LARYNGOLOGY: at 4.30 P.M. (No cases will be shown.)

Discussion on
Paroxysmal Rhinorrhoea.

To be opened by

Dr. J. Freeman and Dr. A. Brown Kelly; followed by Dr. James Adam.

Paper:

Dr. Margaret C. Tod: The Results of Operations on the Nose and Throat in Cases of Asthma.

OBSTETRICS AND GYNÆCOLOGY:

No Meeting of the Section will be held in April.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, March 30th.—9 P.M., Sir Bernard Spilsbury: Wounds and other Injuries in their Medico-Legal Aspect. Last Lettsomian Lecture.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, April 3rd.—8.45 P.M. (at the Miller General Hospital, Greenwich, S.E.), Mr. E. Stanley Rowbotham: Anæsthetics for Operations in the Region of the Mouth and Nose.

MANCHESTER MEDICAL SOCIETY.

WEDNESDAY, April 1st.—4.30 P.M., Discussion on Encephalitis Lethargica. To be opened by Dr. Donald E. Core, Mr. W. St. Clair McClure, Dr. B. J. Ryrie, and Mr. J. Henry Dible.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

TUESDAY, March 31st.—5 P.M., Dr. Hector Cameron: On Some Forms of Vomiting in Infancy. (Second Lumleian Lecture.)

THURSDAY.—5 P.M. (Last Lumleian Lecture.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, March 30th, to SATURDAY, April 4th.—WEST LECTURE HALL, Royal Society of Medicine, 1, Wimpole-street, W. Lectures arranged by the Fellowship of Medicine and open to all members of the medical profession.

Monday, March 30th, at 5.30 P.M., Mr. Ernest Clarke: Myopia—Its Diagnosis and Treatment. Wednesday, April 1st, at 5.30 P.M., Dr. Robert Knox: Demonstration on X Rays in the Diagnosis of Lesions on the Right Upper Quadrant of the Abdomen.—CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd-street, W.C. Lecture-demonstrations in Diseases of the Eye. Daily from 2.30 P.M.—ROYAL NORTHERN HOSPITAL, Holloway-road, N. Intensive Course (second week).

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

TUESDAY, March 31st.—4.30 P.M., Mr. J. Howell Evans: Nature's Reminders of the Humble Origin of Man. (Lantern Lecture.)

FRIDAY, April 3rd.—4.30 P.M., Mr. W. Ibbotson: Nasal Obstruction, Its Causes and Remedies.

Daily: In- and Out-patient Cliniques, Operations, Cliniques in Special Departments, &c.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, April 2nd.—4 P.M., Mr. Fairbank: Fractures.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, April 3rd.—4 P.M., Mr. Armour Brown: Suppuration of the Middle Ear.

MANCHESTER ROYAL INFIRMARY.

TUESDAY, March 31st.—4.15 P.M., Dr. W. Dyson: Bullous Eruptions of the Skin.

FRIDAY, April 3rd.—4.15 P.M., Dr. A. Ramsbottom: Medical Cases. Mr. C. Roberts: Surgical Cases.

Appointments.

ELLIOTT, T., M.B., Ch.B. Leeds, has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Misterton District of the County of Nottingham.

GORDON, J., M.B., Ch.B., D.P.H., Lecturer in Bacteriology at the University of Leeds.

HALL, PERCY, M.R.C.S., L.R.C.P. Lond., Hon. Actino-therapist to the Mount Vernon Hospital.

MACDONALD, J. R., M.B., Ch.B. Edin., Medical Officer to the Durham Board of Guardians.

TURNER, ADAM A., M.B., Ch.B. Aberd., D.P.H., Medical Officer of Health, Finchley.

Essex County Council: FRY, L. S., M.B., B.Ch. Camb., D.P.H., and LORRAINE, N. S. R., M.D. Edin., D.P.H., Assistant County Medical Officers of Health.

Vacancies.

For further information refer to the advertisement columns.

Benenden, Kent, National Sanatorium.—Res. Asst. M.O. £300. Birmingham, Ministry of Pensions, Highbury Group of Hospitals.—Sen. M.O. £500.

Bradford City.—Asst. Sch. M.O. £600.

Brighton, Royal Sussex County Hospital.—Hon. P.

Bristol Royal Infirmary.—Third Hon. Asst. Anaesthetist.

British Guiana.—Asst. M.O.H. £500.

British Hospital for Mental Disorders and Nervous Diseases, 72, Camden-road, N.W.—Hon. Phys.

Cardiff City.—Two Asst M.O.'s. Each £600.

Cardiff, Prince of Wales' Hospital for Cripples and Limbless.—Res. H.S.

Derby County Borough Isolation Hospital and Sanatorium.—Res. M.O. £550.

Derbyshire Royal Infirmary.—H.S. £200.

Devesbury County Borough.—M.O.H. £900.

Durham County and Sunderland and Eye Infirmary, Stockton-road, Sunderland.—H.S. £450.

Hammersmith Parish.—Dist. M.O. and Public Vaccinator. £150. Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. £50.

Hospital for Diseases of the Throat, Golden-square, W.—Hon. Surg. Reg.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S., H.P., and Asst. Cas. O. Each at rate of £50.

Hull and Goole Port Sanitary Authority.—Asst. M.O.H. £750.

Johannesburg, University of the Witwatersrand.—Sen. Lecturer in Dental Anatomy, Physiology, and Histology. £450.

Liverpool County Borough, Local Education Authority.—Three Jun. Asst. School M.O.'s. £600.

Liverpool Eye and Ear Infirmary.—H.S. £100.

Manchester and District Radium Institute.—Asst. Radiologist. £500.

Manchester Royal Infirmary.—Asst. Res. Surg. O. at rate of £200. Ministry of Health, Whitehall, S.W.—M.O.'s. £800.

Newcastle-upon-Tyne City Hospital for Infectious Diseases.—Res. Med. Asst. £350.

Newcastle-upon-Tyne, City and County of.—Tub. M.O. £750.

Newcastle-upon-Tyne, Hospital for Sick Children.—Hon. P. to Elect. Dept.

Paddington Green Children's Hospital, W.—H.P. and H.S. Each at rate of £150.

Prince of Wales's General Hospital, Tottenham, N.—H.S., Spec. H.S., H.P. Each at rate of £150. Jun. H.S. and Jun. H.P. Each at £110. Hon. Surg. Reg. and Hon. Med. Reg. Each £200. Also Hon. Asst. S. to Ear, Nose, and Throat Dept.

Putney Hospital, Lower Common, Putney, S.W.—R.M.O. £150.

Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Obstet. S.
 Queen Mary's Hospital for the East End, Stratford, E.—Hon. Asst. P.
 Redhill, Surrey, Royal Earlswood Institution.—Jun. Asst. M.O. at rate of £250.
 Rochdale Infirmary and Dispensary.—Jun. H.S. £200.
 Royal Chest Hospital, City-road, E.C.—Phys.
 Royal Dental Hospital of London, Leicester-square, W.C.—Hon. Asst. Dent. S.
 Sheffield Royal Infirmary.—H.S. £80.
 Sheffield, University Royal Hospital.—Asst. Pathologist and Demonstrator of Pathology.
 Shrewsbury, Royal Salop Infirmary.—H.S. £250. H.P. at rate of £160.
 South London Hospital for Women, South Side, Clapham Common, S.W.—Clin. Asst. for Ophth. Dept. and Clin. Asst. for Surg. Dept.
 West African Medical Staff.—Medical Officers.

Births, Marriages, and Deaths.

BIRTHS.

JACOB.—On March 22nd, at Bentley, Grays, Essex, the wife of Dr. L. G. Jacob, of a daughter.
 SMART.—On March 19th, at Netherhayes, Seaton, Devon, the wife of A. H. J. Smart, M.B., M.R.C.S., of a son

MARRIAGES.

ANTHONY—COURT.—On March 14th, at Marylebone, Wilfred Mark Anthony, M.B., B.S. Lond., to Dorothy Court, M.B., Ch.B. Edin., youngest daughter of the late Dr. and Mrs. Court, formerly of Bolton.

DEATHS.

HUES.—On March 16th, at Gloucester, Frank Hues, M.R.C.S., Dial House, Handsworth, Birmingham, aged 60.
 LONGHURST.—On March 20th, at the Homestead, Chandlers Ford, Hampshire, Arthur E. T. Longhurst, M.D., aged 94.
 MAKEIG-JONES.—On March 18th, suddenly, at Conisboro, Seaton, Devon, William Makeig-Jones, M.D., J.P., aged 72 years.
 MALDEN.—On March 19th, at Clarendon-place, Leamington Spa, Frank James Malden, M.D., aged 63 years.
 MCGREGOR-ROBERTSON.—On March 17th, suddenly, Joseph McGregor-Robertson, M.A., M.B., C.M., of Buckingham-terrace, Glasgow, W.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

LANCASHIRE'S PANEL PRESCRIPTIONS.—The returns of the Lancashire County Insurance Committee show that the number of prescriptions has risen from 1,787,756 in 1922, to 2,026,460 in 1923 and to 2,438,273 in 1924. The corresponding numbers on the panel were 601,096, 617,577, and 629,907. The cost per prescription in the same order was 9d., 8-65d., and 8-06d. The total cost of medicines supplied to insured persons has risen from £67,070 in 1922 and £73,104 in 1923 to £89,983 last year. The average cost per insured person was 26-77d. in 1922, 28-41d. in 1923, and 34-28d. in 1924. The Southport Insurance Committee report that the total cost of medicines has risen from £2083 in 1922 and £2171 in 1923 to £2545 last year. The number of prescriptions in these years were 57,406, 61,585, and 69,691.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the Committee of the Fund 42 cases were considered and £642 11s. voted to 40 applicants. The following is a summary of the new cases relieved :—

Widow, aged 51, of M.D. Glasg., who practised in Glasgow and died in May of last year. Applicant is left with three sons, ages 19, 18, 13. The eldest is a dental apprentice, the second one a junior clerk at 15s. a week, and the youngest is at school. Applicant's only income is a share of a trust, £32; the estimated profit from one boarder 5s. a week and other charities have granted her £38. Rent and rates come to £126 per annum and the house is rented to May, 1925. Applicant is endeavouring to find a smaller one. Voted £20.

Daughter, aged 59, of M.D. Edin. who held a Government appointment in China and died in 1867. For the last 30 years she has maintained herself by painting Christmas cards, but suffering from neuritis impaired her capacity for earning. Last few years has been subject to hemiplegia which has left applicant partially disabled. Only income an annuity of £50. Rent £27 per annum. Voted £20.

Daughter, aged 28, of M.B. Edin. who practised in Perthshire. Applicant has been trained as a milliner, and her aunt found that her surroundings were unsuitable and removed her. The aunt is now endeavouring to get her to a cousin in Montreal who has a millinery business and has managed to raise the money with the exception of £20. Voted £20.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1.

Notes, Comments, and Abstracts.

RAT-GUARDS FOR SHIPS' HAWSERS.

By CHARLES F. WHITE, M.B., CH.B. MANCH.,
 D.P.H., D.T.M. LIVERP.,

ASSISTANT MEDICAL OFFICER OF HEALTH, PORT OF LIVERPOOL.

IN view of the world-wide distribution of plague the problem of how to prevent the passage of rats between ships and the shore is of great importance in every seaport. No absolutely efficient and at the same time practicable method has yet been devised. Most countries require rat-guards to be fixed on all mooring-ropes, and certainly rats do use ropes as easily as we use the highway. I have seen rats run down an ordinary 8-in. rope at an angle of 45° with perfect confidence and safety. It is therefore necessary to guard ropes, but it is reasonable to suppose that rats will use the easiest means of travelling from ship to shore or shore to ship. Consequently it is futile to put rat-guards on the mooring-ropes of a ship with low free-board lying close against a quay, for naturally the rats will then go over the ship's side. This may be prevented by breasting the ship off four to six feet from the quay. But breasting off adds very considerably to the cost of loading and unloading cargo because of the longer lift necessary. Indeed, in the case of small ships it may mean a double lift. Such a tax on trade is not justified as a routine procedure. Where there is grave risk of the importation of plague infection, all efficient preventive measures are justified, because the interest of the individual ship must be subordinated to the interest of the public health and of other shipping. If plague preventive measures are to be applied,

A. Front view of rat-guard showing three ropes clamped by steel spring. Outside the spring is the collar and below the door, shut and providing no foothold for rats. B. Steel spring for three-rope guard with screw clamp. C. Side view of guard showing projection of collar on each side. D. Reverse side of disc showing hinges and fastening of door. E. Sheet rubber fitting on top of door. F. Guard fixed on mooring-ropes.

not only must the vessel be breasted off from the quay, great care being taken in placing the dummy barges so that rats cannot jump on to them from the bulwarks or through hawse pipe, &c., but also efficient guards must be placed on all mooring-ropes, even wires, and the gangways must be carefully watched or hoisted not only during the night, but at any time when conditions are quiet enough to tempt the rats abroad. Further, ropes hanging down to fenders or swinging loose may provide a means for rats to go to and from ships. The agility of the rat, particularly the black rat, must be seen to be believed. Lastly, undoubtedly rats go to and from ships in cargo, and when plague is suspected, either thorough fumigation must be carried out before the cargo is discharged, or every package that could conceivably harbour rats must be searched on the quay immediately it is landed.

Effective plague prevention is necessarily an elaborate and expensive proceeding, and cannot be applied as a routine to all ships. Some risk must be taken, but it should be reduced to the minimum that is practicable without laying an intolerable burden on trade. In attaining this minimum, rat-guards are undoubtedly valuable, but it is submitted that a general order that all ships should affix them to their ropes is unnecessary and may, in the case of small ships close to the quay, be ridiculous. Rat-guards should be ordered at the discretion of the officers of the Port

Sanitary Authority, but when they are ordered, an efficient type, properly applied and maintained in position, should be insisted on, because many ships' officers appear to think that any piece of tin applied to a rope will pass as a rat-guard.

After various experiments, I have no doubt that the plain sheet metal rimless disc 3 ft. in diameter, when properly fixed and retained at right angles to the rope, presents an almost insuperable obstacle to rats which they will not tackle at all unless hard pressed. I have seen them gain the edge of the disc when driven, but they have always fallen into the dock in attempting to reach the rope on the opposite side.

Hitherto the 3 ft. metal guard has been made in two half sections pivoted near one edge. In application the two halves are separated and the guard is dropped over the rope, the sections then being closed round the rope and held below by a clip. The central collar is then bound close to the rope. The division of the guard down the centre greatly weakens it, with the result that it will not withstand wind or any rough usage, the parts becoming bent in different directions and eventually separating altogether. They are often kept in use long after they are quite ineffective.

A modification of this type of rat-guard has been invented by Messrs. Bird and Sutcliffe in co-operation with the officers of the Liverpool Port Sanitary Authority. The drawings will give a good idea of the essential points in construction. The guard consists of a disc of galvanised sheet iron 1/16 in. thick and 3 ft. in diameter. The edge is left raw—i.e., not wired or turned over. In the lower half is cut a door hinged and so fastened when shut that no foothold is afforded to rats. The door slit leads to the central hole through which the rope passes. Round the central hole is placed a strong collar projecting about 4 in. on each side, and riveted to the disc. In the collar is a strong steel spring clip which can be tightened by the winged nut on the bolt (Fig. B). In application the door is opened and the guard put over the rope so that the latter passes up into the central hole, where a little force is necessary to overcome the spring of the clip. The guard will now hold quite firmly, but the bolt and screw closing the opening of the clip gives additional security. The door is then closed and fastened, the upper edge having a piece of thick sheet rubber attached so as to close completely the central hole whatever the size of rope in use. In the drawings a type of guard suitable for three ropes is shown, such being frequently necessary for large ships. Types are also made for two ropes, one rope or two or three wires, and any guard will fit ropes over a range of about 3 in. difference in diameter, so that any ship may easily be supplied with a set of guards suitable to her requirements.

The advantages of this guard are:—

(1) *Ease of Application.*—The guard is easily and rapidly applied to one, two, or three ropes and needs no binding in position.

(2) *Maintenance of Position.*—Under trying conditions of wind and alternate tightening and slackening of ropes the guard has maintained its position vertical to the rope for a week's test without any readjustment whatever.

(3) *Rigidity.*—Except for the door-opening, the guard is one continuous piece of sheet metal, and is therefore very much stronger than the older type. The riveting of the collar to the disc adds greatly to the stability of the guard, while the steel spring resists the bursting strain when two or three ropes alternately slacken and tighten with the movement of the ship.

The guard costs a few shillings more than the usual pattern, but this should be amply repaid in longer life and much greater efficiency. It is certainly the most satisfactory and practicable rat-guard yet produced.

I am indebted to Mr. J. H. M. Smedley, Chief Sanitary Inspector, Liverpool Port Sanitary Authority, for making the drawings. The guards are manufactured by Fred. Moore and Co., 46-48, Park-lane, Liverpool.

CARE OF THE DESTITUTE IN THE IRISH FREE STATE.

THE Minister of Local Government and Public Health in the Irish Free State has set up a commission to inquire into the relief of the destitute sick and poor, including the insane poor. Under this general reference, particular attention is to be paid to the examination of the existing laws and administration relating thereto. Investigations will be made into the laws dealing with assistance to the sick and poor in their own homes, in order that wasteful expenditure on healthy persons who are incorrigibly idle may be avoided, and a survey will be made of present machinery for affording relief to the following destitute classes: (a) Widows and their children; (b) children without parents; (c) unmarried mothers and their children; (d) deserted children. The existing provision in public institutions for

the care and treatment of mentally defective persons will be examined and the commission will advise as to whether more efficient methods consistent with reasonable expenditure can be introduced, especially as regards the care and training of mentally defective children. Finally, with regard to the cost of relief of the destitute poor generally, the commission will inquire as to whether any change of law is desirable towards securing more equitable dependence on the local rates for persons who, having been normally resident in one poor-relief district, have become a charge upon the rates of another district.

The terms of reference of this commission are wide; they cover not only the Poor-law system (excluding medical treatment) but also the whole asylum system, and provide the opportunity for valuable reforms. It is to be regretted, therefore, that place has been found on the commission for one medical man only, nor is there any member possessed of special knowledge of the care of the insane and mentally deficient.

MEDICAL BOOKS.

WE have received from Messrs. W. and G. Foyle, Ltd., of 121-125, Charing Cross-road, London, W.C. 2, a new edition, dated March, 1925, of their catalogue of new and second-hand books dealing with medicine, surgery, nursing, and pharmacy. This catalogue covers an exceptionally wide range of medical books, and the prices asked for many second-hand copies will appeal to all doctors who feel that the necessary outlay on a medical library is nowadays a serious item of expense.

CALVES' FOOT JELLY.

CALVES' foot jelly is a very useful adjunct to sick-room diet, and the name of Messrs. Fortnum and Mason's, Ltd., 25, Kingsway House, W.C. 2, and 182, Piccadilly, W. 1, who have sent us samples of this invalid delicacy, is a guarantee of careful preparation. In order that the jelly may be of the highest efficiency, it is freshly made every day, and though in cold weather it will keep for 14 days, it is intended for immediate use. The jelly, flavoured with champagne, brandy, or lemon, is put up in screw-stoppered glass jars, the contents weighing six ounces. No preservatives are used in the preparation of the jelly.

ELIZABETH GARRETT ANDERSON HOSPITAL.

If there is one thing about which we were clear, in a world where change of view is often necessary, it was that the cross-word puzzle should not find its way into these columns. Those responsible for the management of the Elizabeth Garrett Anderson Hospital, however, have forced our hands to this extent, that we feel bound to announce that a cross-word competition is in existence in connexion with the Extension Appeal Fund of the hospital. Communications on the subject should be made to Lady Plender, the hon. treasurer, at 144, Euston-road, London, N.W. 1, and should be accompanied by 1s. or more for the list of clues of the E.G.A.H. Cross-word Puzzle.

INCORPORATED SOCIETY OF CHIROPODISTS.

THE annual convention of the society was held at the London Foot Hospital, 98, Charlotte-street, London, W., on March 20th and 21st, where a series of lectures and demonstrations was concluded by a dinner at Restaurant Frascati. Proposing the toast of the Society, Mr. Norman C. Lake said it was no good denying that at present there was a certain regrettable lack of unison between the chiropodist and the medical man, but the former could do much to bring about greater co-ordination by taking full advantage of the facilities offered by the society for gaining a sound knowledge of the rudimentary principles underlying medicine and surgery. The fault, however, was not all on one side. The medical profession were also to blame. They required educating up to the value of chiropody. During the course of his hospital practice in particular he saw large numbers of cases of various foot deformities, and those which were not sufficiently severe to demand surgical treatment, but which he was afraid the medical practitioner was generally too busy to devote proper attention to, he referred, with highly satisfactory results, to the clinic at 98, Charlotte-street. Thus many of the poorer class who had hitherto worked under great difficulty owing to foot troubles had been enabled to carry out their duties in greater comfort. That was a very valuable service which ought to be more widely known and appreciated. Dr. J. H. H. McLeod, Dr. G. Slot, Mr. T. H. Openshaw, and Dr. E. P. Cumberbatch were amongst those present, and in the course of their speeches testified to the necessity for greater use being made of qualified chiropodists not only in private practice, but in hospitals and public clinics.

In a recent advertisement of Messrs. H. K. Lewis and Co.'s publications, the price of "Lateral Curvature of the Spine," by R. W. Lovett, was inserted as 2s. 6d. net. The correct price is 12s. 6d. net.

PROPRIETARY MEDICINES BILL: SECOND READING IN THE HOUSE OF LORDS 22	

THE SALE OF PATENT MEDICINES

IN 1914, a Select Committee of the House of Commons was appointed to consider and inquire into the question of the sale of patent and proprietary medicines and medical preparations and appliances, and advertisements relating thereto, and to report what amendments, if any, in the law are necessary or desirable. The Committee consisted of the following: Mr. Charles Bathurst, Mr. Cawley, Dr. Chapple, Sir Henry Dalziel, Mr. Hayden, Mr. Ingleby, Mr. Glyn-Jones, Mr. Haydn Jones, Mr. Lawson, Mr. Lynch, Sir Philip Magnus, Mr. Newton, Sir Henry Norman, Mr. O'Grady, and Mr. Hill-Wood, with Sir Henry Norman as chairman, and they were empowered to send for persons, papers, and records, and to order analyses. The following is the Report agreed upon by the Select Committee of the House of Commons and issued to the press on August 26th, 1914.

I.

REPORT OF THE SELECT COMMITTEE ON PATENT MEDICINES

1. Your Committee, during the three sessions of Parliament over which their labours have extended, have held 33 public sittings, and have examined 42 witnesses, of whom more than 14,000 questions have been asked.

2. Of these witnesses nine represented Government Departments, either of this country or Australia, 11 were medical men, five were analysts, four were wholesale or manufacturing druggists, and nine were manufacturers or proprietors of proprietary medicinal preparations. Fourteen analyses have been made for us.

3. In the evidence given before your Committee, the following public authorities or associations have been represented: The Customs and Excise, the Privy Council Office, the Home Office, the Local Government Board, the Director of Public Prosecutions, the Government Laboratory, the Commonwealth of Australia, the General Medical Council, the Royal Society of Medicine, the Royal College of Physicians, Edinburgh, the British Medical Association, the Pharmaceutical Society, the White Cross League, the Proprietary Articles Section of the London Chamber of Commerce, the Association of Wholesale Druggists, and the Association of Medical Herbalists.

Your Committee have also received resolutions from representative bodies, and a large number of communications from private individuals.

4. Your Committee have received from the Foreign Office, the Colonial Office, and from other sources, information as to the existing state of the Law and its administration, in relation to the subject matter of their inquiry, in the principal foreign countries, and in the Dominions. The greater part of this information will be found in the Appendices, but we think that it may be useful, before considering the sale and advertisement of secret remedies in this country, to present the following summary of the information supplied to us of existing laws in foreign countries and British Dominions.

THE LAW IN FOREIGN COUNTRIES.

5. (1) *Germany*.—In Germany a medicine itself cannot be patented, but only the process used in its production; "pharmaceutical specialities," however, can be protected by registered trade-marks. The

retail trade in a number of "pharmaceutical specialities" is governed in the several Federal States by regulations based upon decisions of the Bundesrat of 1903 and 1907.

Under the regulations a number of preparations are grouped by name in two Schedules A and B, and these may only be sold in pharmacies. Those in Schedule A require a medical prescription as a condition of their sale if they contain drugs of powerful effect, or if the pharmacist is ignorant of their composition. For those in Schedule B, a prescription is in every case necessary. None of these preparations may be publicly advertised or recommended, nor may recommendations or testimonials be included in the package or covering with which they are sold.

These regulations are supplementary to the general regulations governing the conditions under which drugs of powerful effect may be sold, whether proprietary preparations or not.

(2) *Austria*.—In Austria the effect of the law appears to be that no proprietary medicinal preparation may be retailed, the composition of which is unknown, and which has not been officially authorised for sale.

(3) *Hungary*.—In Hungary no secret remedy or pharmaceutical speciality may be sold without the sanction of the Government Department concerned; known and approved remedies may not be sold under changed names; prices must be fixed according to the wholesale prices of drugs; and the recommendation issued with the remedy must also be officially approved.

(4) *France*.—In France the sale of secret remedies, whether of French or foreign origin, is prohibited by law, though it would appear to be legal to sell known and approved remedies under other names, provided the remedy is not advertised in such a way as to give the impression that it is a new discovery. A decree of 1810 provides machinery by which inventors of new remedies or compounds may obtain official recognition of and remuneration for their discoveries.

(5) *Italy*.—In Italy all patent medicines must be submitted, with their prescription, to the Ministry of the Interior, and the prescription must accompany all packets, &c., offered for sale. False or grossly exaggerated statements, whether of contents or effects, are punishable by fine. Your Committee, however, are informed that the law is not rigidly

enforced, and that an approximate statement of the contents of a preparation is considered sufficient.

(6) *The United States.*—In the United States the sale of medical preparations is regulated by the Food and Drugs Acts. There appear to be no separate State laws dealing with the subject. Proceedings were taken under the Act of 1906 in several cases against vendors of fraudulent nostrums for which extravagant claims were made, their drugs were declared "misbranded," and the vendors were fined. A decision of the Supreme Court, however, in 1911 confined the term "misbranding" to false statements regarding the contents of a medicine, and in consequence an amending Act was passed in 1912, Section III. of which provided that that part of Section 8 of the Food and Drugs Act of 1906, defining what shall be misbranding in the case of drugs, should be amended by adding the following paragraphs: "That the term 'misbranded' as used herein shall apply to all drugs or articles of food or articles which enter into the composition of food the package or label of which shall bear any statement, design or device regarding such article, or the ingredients or substances contained therein which shall be false or misleading in any particular, and to any food or drug product which is falsely branded as to the State territory or country in which it is manufactured or produced. That for the purposes of this Act an article shall also be deemed to be misbranded—in the case of drugs:—*First*: If it be an imitation of or offered for sale under the name of another article. *Second*: If the contents of the package as originally put up shall have been removed in whole or in part, and other contents shall have been placed in such package, or if the package fail to bear a statement on the label of the quantity or proportion of any alcohol, morphine, opium, cocaine, heroin, alpha or beta eucaine, chloroform, cannabis indica, chloral hydrate or acetanilide, or any derivative or preparation of any such substances contained therein. *Third*: If its package or label shall bear or contain any statement, design or device regarding the curative or therapeutic effect of such article or of any of the ingredients or substances contained therein, which is false and fraudulent."

THE LAW IN BRITISH DOMINIONS.

6. (1) *Australia.*—Your Committee have heard much valuable evidence regarding the law and its administration in Australia from Dr. W. Perrin Norris, who until recently was Director of Quarantine under the Commonwealth Government, and is now Chief Medical Officer for the Commonwealth in London, and from Mr. H. E. Neal, of the High Commissioner's Office.

Under this administration strict supervision is exercised upon all printed matter, labels, &c., accompanying medicines imported into the Commonwealth; extravagant or otherwise objectionable statements are required to be modified or excised; and if necessary the goods are not allowed to be imported until such modifications have been made. In a few cases medicines or medical appliances have been refused admission absolutely. Your Committee are informed that this is carried out without any considerable difficulty, and they have in the course of their inquiry noticed numerous cases in which there are substantial differences between the labels, &c., accompanying goods sold in this country, and the same goods as sold in Australia. (See Par. 52.) It is to be noted, however, that the action of the Commonwealth authorities is confined to dealing with the goods at the port of entry, and the control of the conditions of retail sale, or internal manufacture, is in the hands of the respective State Governments; but it would appear that the State laws tend to approximate to those of the Commonwealth, and in some cases even to go beyond them. Thus, in Western Australia, under recent statutory regulations, the formula

of every proprietary medicine is required to be stated on the label, or alternatively, deposited with the Department of Public Health. In New South Wales, by the Pure Food Act of 1908, a drug is declared to be falsely described when it "bears a statement design or device regarding such drug or the ingredients or substance contained therein, which is false or misleading in any particular." Under the regulations, moreover, if any one or more of some 42 scheduled drugs or poisons be contained in a preparation, the name of the drug, and the proportion of it that is present, must be stated on the label. In Tasmania, under the Food and Drugs Act, 1910, the health officer may examine and report upon drugs and appliances advertised, and may compare the results with any advertisement; the reports may be published in the Gazette and newspapers; and the Governor may prohibit the advertising or sale of any drug or appliance which is held to be injurious to health or "which by reason of its inactivity or inefficiency is useless for the advertised purpose of cure."

(2) *Canada.*—In Canada legislation is on different lines, every importer, manufacturer or agent being required to procure annually a numbered certificate of registration, and the label being required to bear the number and name under which the medicine is registered; moreover, if any of certain specified drugs are present in a greater proportion than is officially authorised, the names of such drugs must be conspicuously printed on the labels and wrappers.

7. The sale of remedies of which the composition is secret is thus restricted in varying degrees by law in the principal foreign countries, and in the British Dominions. This was confirmed to us in evidence by a number of proprietors of secret remedies, who giving various reasons for their action, informed us, that as a matter of fact they export to foreign countries little or none of their products. Of the law in the United States and Australia we shall have occasion to speak later. We pass now to the law and its administration in the United Kingdom.

THE LAW IN THE UNITED KINGDOM.

8. We have found much difficulty in arriving at a clear appreciation of the law and its administration. In support of this statement it may suffice to refer to the evidence of the witness from the Home Office, who admitted that there was no department of the Government which from its own experience, or from the knowledge officially obtained by it, could give us information or advice regarding the general scope of our inquiry. The law is contained in fragmentary form in parts of a number of overlapping statutes dating from 1804; when administered at all it is administered by a number of Departments of State of whose differing functions there is neither definition nor consistent practice; and owing to the rare occasions on which cases under the Statute Law have been brought before the courts, there is no body of precedents to afford private or official guidance.

9. Fiscal duties in respect of medicines were originally imposed in 1783. The present law requiring a licence to sell, or imposing a duty upon medicine sold, dates from three Acts of 1802, 1804, and 1812. In 1864 the duty on the licence was made a duty of Excise, and in 1875 a uniform duty of 5s. was imposed for the licence. There are two principal exemptions from duty, namely:—

(1) Pure drugs, that is, drugs vended entire, without any mixture or composition with any other drug, by any qualified person, or person holding a licence; and (2) well-known and admitted remedies. (As a matter of fact, the Courts have only decided this exemption in one case—namely, ammoniated tincture of quinine.) There is no duty upon these remedies in Ireland, if manufactured there.

The scale of duties, unchanged since 1804, is as follows:—

Medicines of the price or value of 1s. or under, 1½d.

Medicines of the price or value exceeding 1s., but not exceeding 2s. 6d., 3d.

Medicines of the price or value exceeding 2s. 6d., but not exceeding 4s. 6d., 6d.

Medicines of the price or value exceeding 4s., but not exceeding 10s., 1s.

Medicines of the price or value of 10s.–20s., 2s.

Medicines of the price or value of 20s.–30s., 3s.

There were originally two higher classes of duty, under 50s. and above 50s., but these have ceased to be demanded and the labels are no longer printed.

10. The sale and advertisement of patent and proprietary medicines, apart from fiscal provisions and from the Common Law, may fall under several Acts of Parliament, the administration of four Departments of State, and the activities of two statutory bodies.

(a) Acts of Parliament.

(1) *The Stamp Acts*.—The duties upon medicines are Medicine Stamp Duties under the Stamp Acts.

(2) *The Pharmacy Acts, 1868 and 1869, and The Poisons and Pharmacy Act, 1908*.—A poison is any drug named in the schedules to the latter Act. Nothing else, in the view of the law, is a poison. Any medicine containing a poison must bear the word "Poison," or if containing a poisonous substance mentioned in Section 5 of the former Act, the word "Poisonous." Medicinal preparations may also come within the terms of the Arsenic Act, 1851.

(3) *The Merchandise Marks Act, 1887*.—Under this Act it is (shortly) an offence to apply a false trade description to goods, or to sell goods so falsely described, unless the person prosecuted proves that he acted innocently in the matter.

(4) *The Sale of Food and Drugs Acts, 1875 and 1899*.—Under Section 27 of the former Act it is an offence wilfully to give with an article sold a label falsely describing such article. But under Section 6 of the same Act an offence shall not be deemed to be committed "where the drug or food is a proprietary medicine or is the subject of a patent in force." The appointment and duties of public analysts, and the procuring and analysing of samples of drugs by local authorities are prescribed by these Acts.

(5) *The Indecent Advertisements Act*.—Under this Act it is an offence to affix or inscribe on any house or building an advertisement relating to disease connected with sexual intercourse.

(6) *The Larceny Act*.—Under Section 88 it is an offence to obtain money by false pretences from any person with an intent to defraud.

(b) Departments of State.

(1) *The Privy Council Office*.—The Privy Council exercises a certain amount of supervisory and regulative influence through their charter or otherwise upon the qualifications and conduct of doctors, dentists, chemists, veterinary surgeons, and midwives. An Order in Council, following upon a recommendation of the Pharmaceutical Society, is necessary to add a drug to the schedules of poisons.

(2) *The Home Office*.—The Home Secretary answers questions in the House of Commons, on behalf of the Lord President of the Council, on the general subject of proprietary medicines, and he has power to direct the Director of Public Prosecutions to take proceedings. Complaints of fraud would properly be made to the Home Office, as the general supervising authority over the police.

(3) *The Local Government Board*.—This department controls the administration of the Sale of Food and Drugs Acts by the 234 local authorities of England and Wales.

(4) *The Patent Office*.—The Comptroller-General informed us that 312 patents granted to 1912 for medicine and medicinal preparations are in force. There are very few patents of the remedies to which our inquiry was specially directed, as a patent cannot be secured without (a) proof of usefulness and novelty, and (b) disclosure of formula.

(c) Statutory Bodies.

(1) *The General Medical Council*.—This body is charged by the Medical Act, 1858, with publishing from time to time the "British Pharmacopoeia," an authoritative standard and guide to the uniformity and purity of drugs employed by medical men. The last edition was published fifteen years ago. A new edition is at last in the press.

(2) *The Pharmaceutical Society*.—This body, created by Royal Charter in 1843, is charged by the Pharmacy Acts with a measure of control over the sale of proprietary articles containing scheduled poisons. It has no powers in relation to other proprietary articles. It moves the Privy Council to add to the schedule of poisons.

11. The foregoing summary, if left without comment, might be thought to indicate an adequate body of law and administrative authority to deal with the subject of our inquiry. This is far from being the case. So far as the prevention of fraud is concerned, the before-mentioned statutes or powers are of little value. To show this in detail in each instance would be to overload our Report with details. We confine ourselves, therefore, to a brief indication of the facts or the authority upon which we base the above opinion.

12. There is no Department of State officially concerned with the sale and advertisement of these articles. The witness from the Home Office said to us: "This is one of many subjects which no Department of State claims as its own." He further said: "The Home Secretary, as regards patent and proprietary medicines as such, has no powers or duties." And he added: "Proceedings for fraud against proprietors or vendors of proprietary medicines on the ground that they cannot cure the diseases they mention are practically unknown." As regards the Privy Council in this connexion, it is merely a clerical vehicle for passing on any question to some other department, possessing itself neither knowledge nor adequate staff to deal with it. And even its function of securing Order in Council is exercised with such laxity that whereas the Pharmaceutical Society passed resolutions in 1882, 1886, 1893 (moved by the Local Government Board), and 1899, requesting that various poisons, including carbolic acid, which was responsible for 200 fatalities a year, should be added to the schedule of poisons, it was not until 1900 that this recommendation was carried out in part. It thus took the Privy Council 18 years to add carbolic acid to the schedule of poisons. The President of the Pharmaceutical Society not unnaturally expressed to us the opinion that "a change in the law, or, at any rate, a great change of procedure, is urgently necessary."

13. The Merchandise Marks Acts give no specific authority to local authorities to prosecute for a false trade description, and no private individual has yet seen fit to do so in respect of a proprietary medicine. Moreover, an action would only lie in the case of a medicine not being what it was alleged to be; for instance, a drug not quinine described as being quinine. Further, it does not apply to fraudulent advertisements, except in so far as such advertisements accompany the goods.

14. In the Sale of Food and Drugs Act, Section 6, subsection (2) specifically exempts proprietary and

patent medicines from its operations. Even if this exemption were abolished this section of the Act would still be practically useless, as a purchaser asking for X's pills and getting X's pills would be getting an article "of the nature, substance, and quality of the article demanded."

15. The Indecent Advertisements Act does not include advertisements in newspapers.

LEGAL AND OFFICIAL ANOMALIES AND CURIOSITIES.

16. The anomalies and curiosities of the law and official practice are numerous and remarkable. For example, under the Stamp Act foreign medicines are liable to duty merely because they are foreign, but since 1885, when Mr. Childers was Chancellor of the Exchequer, the Commissioners of Inland Revenue have disregarded the difference between British and foreign preparations as a concession, according to one witness, to those who contended that the duty violated the doctrines of free trade. Again, any number of different names may be secured as trade-marks for the same drug. Thus "soamin" is "atoxyl," and the drug acetyl-salicylic acid is sold as "Aspirin," "Saletin," "Salacatin," "Xaxa," &c., and a chemist receiving a prescription with "Xaxa," for instance, on it, cannot substitute acetyl-salicylic acid, though he may know the two substances to be identical, without rendering himself liable to an action for damage by the proprietor of "Xaxa." Acetanilide is sold as "Antikamnia" (the drug sold in America under this name was formerly acetanilide, but in consequence of a change in the law it is now phenacetin in America, but is still acetanilide in this country), "Ammonol," "Antitoxine," and "Phenalgin"; "phenolphthalein" simple or compound, is sold as "Aperione," "Laxans," "Laxatin," "Laxatol," "Laxatoline," "Laxiconfect," "Laxoin," "Laxophen," "Paraphthalein," "Phenolax," "Prolicin," "Purgen," "Purgo," "Purgolade," "Purgella," and "Purgylum"; formamine or urotropine (hexamethylene-tetramine, or commercial varieties of it) is sold under the proprietary names of "Aminofarm," "Cystamin," "Metramine," "Urisol," "Uritone," "Xametrin," "Vesalvine," &c. Again, the retailer of "Wincarnis" must hold an off wine licence (costing at least £2 10s.), but the Commissioners of Inland Revenue decided that the addition of one gr. of quinine hydrochloride to the fluid oz. makes it a medicated wine, and the retailer need only hold a patent medicine licence (costing 5s.). Thus the proprietors of a medicated wine are naturally induced to add precisely that amount of quinine which the Commissioners decide will enable it to be sold by retailers holding the less expensive licence. Again, a manufacturer of dutiable preparations can export them to himself in a foreign country without paying British duty; if he exports them to another person he must pay duty. But he can transfer them to himself in Ireland and export them from there to any person without paying duty upon them. Again, in all cases where the name of an ailment is mentioned in connexion with a medicine, the Commissioners have since 1902 required duty to be paid; where no ailment, but only the organ of the body which is the seat of the ailment is mentioned, the medicine is not dutiable. Thus "cough mixture" is dutiable, "chest mixture" is not; "liver tonic" is dutiable, "liver mixture" is not; "corn paint" is dutiable, "toe paint" is not; "headache powder" is dutiable, "head powder" is not. Millions of powders for headache now escape duty under this decision, the name having been changed from the former to the latter. An alleged cure for asthma only fails to escape duty because no organ of the body can be named as specially the seat of that ailment. Asthma cigarettes, however, are not regarded as a preparation "to be used or applied externally or internally, as a medicine or medicament." Therefore, they pay no duty. But smelling salts are dutiable. Again, if the original maker of a well-known medicine

in which no proprietary rights are claimed affixes a label recommending its efficacy, he must pay stamp duty. But a retail chemist may purchase it from him and affix such a label without paying duty. Again, there is no duty upon waters containing carbonic acid gas, or solid preparations for impregnating water with this gas. The Court ruled, therefore, that powders like "Eno's Fruit Salt," "Kutnow's Powder," "Pyretic Saline," &c., are not dutiable, though proprietary medicines recommended for ailments, on the ground that when mixed with water they effervesce by the generation of carbonic acid. Again, an advertisement, not in itself indecent, relating to complaints arising from sexual intercourse, becomes indecent in law if affixed or inscribed anywhere, but not if published in a newspaper, put in a letter-box, or thrown down an area; and such advertisements are frequently exhibited in shop windows.

The above examples illustrate the remark made to us by the solicitor to the Chemists' Defence Association that the existing state of the law constitutes "a financial and legal chaos," and the view expressed by the Solicitor to the Customs and Excise, who said, "We have long felt that the whole of this law is very much out of date." From the traders' point of view it is very difficult to know what articles are dutiable and what are not, and the Commissioners themselves confess that they do not enforce the Act strictly. Finally, to compare British with foreign law in one instance, we may refer to the case of the American Macaura. He is stated by one witness to have gained £60,000 by his recent campaign in England of advertising, exhibiting, and selling an alleged vibratory cure for many ailments, whereas for the same procedure in Paris he has just been sentenced to three years' imprisonment and a fine of £120.

PROSECUTIONS FOR FRAUD.

17. Successful prosecutions for fraud in connexion with the sale of secret remedies have been so few as to be negligible. In the first place, as we were informed by the Assistant-Director of Public Prosecutions, at present there is no person whose duty it is to see whether patent medicine manufacturers are making fraudulent claims. And when a prosecution is undertaken, it usually breaks down for one of two reasons: (1) It is impossible to prove guilty knowledge—that is, "wilful" misstatement, often because the medicine is usually sold by persons ignorant of their composition. (2) The defendant is able to produce witnesses who state that the medicine has been beneficial to them. A drug or appliance, for example, is advertised to cure deafness. It may be a drug or treatment which is commonly used by the medical profession to benefit specific or simple cases. The vendor can thus produce a few cases which have derived benefit, whereas in thousands of other cases it is a sheer fraud. (3) In grave cases, like drugs sold to procure abortion, the prosecution could hardly produce a witness to say, "I bought this drug believing it would enable me to commit a crime; I found it would not, and I am defrauded." We have privately brought to the notice of the Director of Public Prosecutions several cases obviously of the most fraudulent or offensive description, and have requested him to prosecute. In each case, with every desire to do so, he has after careful consideration explained to us the legal grounds on which, in his opinion, it would be impossible to secure a verdict.

18. One example of an unsuccessful prosecution of a retail vendor may usefully be given. In 1907 the Liverpool Corporation made a praiseworthy attempt to punish fraud in the case of a preparation, the materials of which, according to the medical officer of health, cost about a penny and which was sold for 2s. 9d. The retail vendors were prosecuted on the ground that the statement on the label that the preparation "contains the active ingredients and digestive qualities of the gastric juice in a highly

concentrated and permanent form," was false and fraudulent. An analyst's certificate was produced, showing the contents to be water, with traces of phosphoric acid, hydrochloric acid, nitric acid, and calcium phosphate, flavoured with chloroform and a vegetable bitter, and coloured with cochineal. The only part of this resembling the gastric juice was the minute quantity of hydrochloric acid. But it was impossible to prove guilty knowledge on the part of the vendors, the case against them was withdrawn, and they were allowed five guineas costs. It is not surprising that the medical officer of health of the City of Liverpool should add, in supplying us with the above facts, "Further analyses have been made of patent medicines, but no legal proceedings have been taken." It should be pointed out that the prosecution was not taken against the manufacturers of the remedy.

THE INADEQUACY OF EXISTING LAW.

19. In opposition to any change in the law affecting the sale or advertisement of secret remedies, it was contended to us on behalf of the Proprietary Articles Section of the London Chamber of Commerce that false statements or false pretences in respect of such remedies are already adequately dealt with either by Common Law or by certain existing Acts; and that adequate powers of prosecution are already vested in certain officials and Departments of State. After most careful and prolonged consideration, in public and in private, we are convinced that this is not the case.

20. By strict interpretation of existing statutes, of the precedents of Common Law, or of the authority of officials and departments, considerable powers of prevention and prosecution may exist nominally. But we are satisfied that the difficulties of bringing these powers into successful operation are so numerous and great that for all practical purposes the sale and advertisement of secret remedies (unless they contain scheduled poisons) is unrestricted by law in this country.

21. In the final support of this view we would quote the two most weighty official opinions available to us. Mr. Guy Stephenson, Assistant Director of Public Prosecutions, assured us that "the difficulty of successfully prosecuting for any false statement with regard to the powers of a medicine, is almost insuperable." He then gave evidence as follows:—

Chairman: That is to say, the law is practically non-existent, speaking generally?

Witness: If you like to put it in that way.

Chairman: Or, in other words, the vendors of patent and proprietary medicines can practically do what they like, so long as they keep outside the bounds of gross and obvious impropriety?

Witness: It would seem so—yes.

And Mr. MacFadden, M.B., of the Local Government Board, gave the following evidence:—

Chairman: In fact, we may take it then, as a general summary of your view, that the existing laws are not operative as regards this class of articles, and that they must almost necessarily be inoperative?

Witness: That is so.

22. The situation, therefore, as regards the sale and advertisement of patent and proprietary medicines and articles may be summarised in one sentence as follows. For all practical purposes British law is powerless to prevent any person from procuring any drug, or making any mixture, whether potent or without any therapeutical activity whatever (so long as it does not contain a scheduled poison), advertising it in any decent terms as a cure for any disease or ailment, recommending it by bogus testimonials and the invented opinions and facsimile signatures of fictitious physicians, and selling it under any name he chooses, on the payment of a small stamp duty, for any price he can persuade a credulous public to pay.

STATISTICS OF THE TRADE IN PROPRIETARY REMEDIES.

23. We pass now to an examination of the trade in proprietary remedies as it exists in this country, and in the first place, to its fiscal and financial side. The yield of the duties was, to March 31st, 1914, in respect of 43,156 licences, £10,791, and in respect of duties upon medicines apart from licences, for 1912, £327,856; for 1913, £328,318; for 1914, £360,376, thus showing an increase of £31,958 during the past 12 months, the greatest advance in one year for many years. Of the whole revenue all but a very small sum was paid in England. The number of medicine stamps issued in the year ending March 31st, 1908, was 41,757,575, of which 33 millions were for 1½d., 7½ millions for 3d., and one million for 6d. For the year ending March 31st, 1914, it was 44,427,166, of which 34 millions were for 1½d., nearly 9 millions for 3d., and a little over one million for 6d. The increase is thus rather over 2½ millions in six years. The Customs and Excise informed us that it was impossible to tell from these figures what the total sales amounted to, and therefore whether the consumption is increasing or not. But on the assumption that all the 1½d. stamps were put upon medicines retailed at 1s. 1½d. (which is not entirely the case), the sales of these would reach about £1,930,000, and that all the 3d. stamps were put upon medicines retailed at 2s. 9d., the sales of these would be about £1,275,000, or nearly £3,200,000 for these two classes of preparations alone. The President of the Pharmaceutical Society of Great Britain, speaking with 36 years' continuous experience as a retail chemist, informed us that the sale of proprietary remedies has very largely increased during the past ten years.

24. We would draw attention, however, to the probability that the sales of secret remedies will tend to decrease from the operation of the National Insurance Act. Now that the millions of insured persons can obtain medical advice, prescriptions, and drugs free of cost, they will naturally be less likely to attempt self-medication in order to save doctors' fees.

25. There is no record at the Custom House of the importation of these preparations. It is therefore impossible to discover from our own records the respective proportion of home-made and imported remedies, but without doubt a large quantity comes from the United States. Prof. Cushny stated that this has increased of late owing to greater restrictions upon their sale there. As he put it, "We are getting the benefit of the legislation of the United States. We are getting a lot of quack remedies which were formerly confined to the United States." These enter free of all import duty except upon their content of materials in themselves dutiable. One witness quoted an official American statement to the effect that about 15,000,000 packages of proprietary remedies were exported from the United States to this country in 1911, of a total value of about £400,000.

26. While the trade in certain classes of secret remedies is carried on, often as mail-order business only, with trifling capital, in other cases the amount of capital invested in manufacturing is very large. The annual turnover of the proprietor of "Beecham's Pills," selling over a million pills a day, Sundays included, is about £360,000 a year. The proprietors of "Seigel's Syrup," who have sold 100 million bottles in 40 years, pay upwards of £40,000 a year in wages alone.

27. In most cases the principal expenditure in connexion with secret remedies is in advertising. The proprietors of "Wincarnis," for example, spend thus £50,000 a year, employing between 30 and 40 persons in their advertising bureau. "Elmer Shirley," a witness informed us, spent at one time £1000 a week. The proprietors of "Daisy" powder, a comparatively small business, spend £3000 a year. The late A. L. Pointing, a well-known swindler, is believed to have

spent £20,000 a year in advertising an "alcohol cure" called "Antidipso"—at his death he left £80,000. The Proprietary Articles Section of the London Chamber of Commerce estimates that £2,000,000 is spent annually in this country in advertisements of proprietary medicines.

THE PRESS AND SECRET REMEDIES.

28. It may be convenient to speak at this point of the relation of the newspaper and periodical press to secret remedies. As so large a sum as £2,000,000 or more is spent annually in advertisements of these remedies in one form or another of advertising, the trade is naturally of great importance to newspaper proprietors. In the case of most newspapers these advertisements constitute one of the most considerable sources of income, while a number of small provincial newspapers could probably hardly exist at all without secret remedy advertisements. All periodicals exercise some censorship over these advertisements. With a few, mostly weekly sporting low-class prints, fear of prosecution alone dictates a certain caution. Other papers draw a line of varying strictness. One newspaper only, the "Spectator," we were informed, wholly excludes these advertisements, but a few daily papers also practically close their columns to them. The respectable press, speaking generally, refuses all advertisements having any suggestion of impropriety. Some papers of the so-called "religious press," we are told, show a wider hospitality to secret remedy advertisements, and many of an objectionable character have been found in its columns. It is also lamentably true that the cheap so-called "home" weeklies, intended for the reading of girls and young women, contain advertisements of a grossly improper nature. Many improper advertisements from weeklies, sporting prints, "religious" and "home" papers, were exhibited to us—including 19 advertisements of drugs obviously intended to be used as abortifacients in one provincial Sunday paper—but none of this character from high-class dailies or weeklies. We are convinced that the proprietors of the better class of newspapers and secret remedies alike would welcome a drastic suppression of suggestive or improper advertisements. The foregoing observations do not refer to the advertisements of swindlers like Macaura, the "eye quacks," the "deaf quacks," the cancer-curers, the consumption-curers, the electric belt makers, the curers of rupture without operation, or "fakirs" generally. As regards these classes, most newspaper proprietors do not regard it as incumbent upon them to test the good faith of secret remedy advertisers any more than of advertisers of other goods, though a few of the leading papers exercise a very severe censorship upon advertisements of this kind also. We must point out further, in this connexion, that the large sums received for the advertisement of secret remedies lead newspapers, either from discretion or under compulsion, to exclude from their columns criticism or discussion of secret remedies. When the British Medical Association, for example, issued their volume, entitled "Secret Remedies," containing analyses, costs, &c., of a large number of proprietary medicines, not only was the volume not noticed editorially by most papers, but even an advertisement of it was declined by many journals, some of them of the highest class. A trial in Edinburgh in the course of which the judge described the business of the proprietors of "Bile Beans" as "based on unblushing falsehood for the purpose of defrauding the public," was, we were informed, with few exceptions not reported in the Press, and the remedy still has a considerable sale. The extent to which criticism of secret medicines is excluded from the Press may probably be judged by anyone who will take the trouble to see how much attention is bestowed by the newspapers upon your Committee's Report.

29. With regard to the advertisements in the Medical Press, we consider that adequate censorship

has not in all cases been exercised, as, indeed, was admitted by Dr. Cox, the representative of the British Medical Association, and instances to this effect will be found in the evidence we received.

THE ANALYSIS OF SECRET REMEDIES.

30. Mention of the volumes called "Secret Remedies" leads us to speak of the analysis of proprietary and secret remedies. It is vital to many proposals to deal by law with secret remedies on the ground of either their injurious or their inactive nature, that their composition should be determinable by analysis. Eminent analysts appeared before us in support of the cases for and against these remedies, but as might have been anticipated their views differed widely, and they did not fail to draw our attention to each other's unsatisfactory methods and erroneous results. We received, however, valuable independent guidance from the Government Chemist, Dr. Dobbie, and his first-class analyst, Mr. C. Simmonds.

31. It is asserted by expert analysts representing the proprietary medicine trade that no known methods of analysis will enable the composition of many secret remedies to be accurately determined. Consequently, it was claimed, the analyses published in "Secret Remedies" are incorrect in many cases. In one or two instances the makers informed us in confidence of ingredients which the British Medical Association analyst or the Government Chemist had failed to identify. Where there is an undiscovered ingredient the maker claimed special virtues for it—which he would possibly not do, as one witness suggested, if it were named. To this aspect of analysis, obviously of the greatest importance, we gave prolonged and most careful attention, and basing our view upon consideration of much technical evidence, we have reached the following conclusions.

A large proportion of drugs consists of inorganic substances, or compounds of inorganic with organic substances. Practically all of these are recognisable, and so far as concerns the inorganic substances themselves, determinable—that is, not only the substance recognised but also its quantity determined—by competent analysis. A further group consists of manufactured compounds, and these are practically all recognisable by analysis, even in somewhat complex mixtures. There remains a group of vegetable extracts, of which dandelion and gentian are familiar examples. But even simple vegetable extracts are really highly complex bodies, and the exact composition of these is still unknown to chemistry. Unless one of these, therefore, possesses a marked smell or taste, or if, possessing such, its smell or taste is masked by the greater smell or taste of some other similar substance, it cannot in many cases be specifically identified. The difficulty of identification, moreover, increases rapidly in proportion to the number of such extracts in a mixture, and when a large number, say eight or ten, are mixed together, even separate detection is impossible, and accurate determination out of the question. What is relied upon, however, in vegetable extracts for medicinal effect is often an alkaloid or mineral constituent, and these can be accurately discovered and determined. Further, subgroups of this group possess in common an active principle which can be recognised and which serves to identify the substances of the particular subgroup. For example, emodin is said to be the active principle of rhubarb and half a dozen other vegetable extracts.

32. One important practical result of the foregoing is that any maker of a secret remedy, by mixing together, whether with or without scientific or therapeutical knowledge, a number of vegetable extracts, can truthfully state that the composition of his remedy cannot be discovered by analysis. A mixture of tinctures, infusions, decoctions, or extracts of such familiar yet complex bodies as treacle, honey,

aloes, cinnamon, liquorice, linseed, coltsfoot, cubebs, pepper, horehound, ginger, gentian, dandelion, rhubarb, saffron, &c., may defy all chemical, microscopic, spectroscopic, olfactory, or physiological analysis. While a mixture, therefore, may have a therapeutical value, it may also be made to defy the analytical exposure of a fraudulent claim of therapeutical value. There are thus distinct limits to analysis, but in practice these limits are narrower than would appear, for in a large majority of cases the essential nature of the principal constituents of any medicine can be detected with almost perfect certainty and determined with reasonable accuracy, given skill, time, and a sufficient quantity of material.

ORGANISATION OF THE TRADE IN PROPRIETARY REMEDIES.

33. The trade in patent and proprietary medicines is represented in Great Britain by the Proprietary Articles Section of the London Chamber of Commerce, which contains over 300 manufacturers or vendors of such articles. Membership of the Section is open to any person in the trade, proposed and seconded by members. No control of any kind is exercised by the Section over the nature of the remedies sold or the claims made for them. This body presented to us the case for proprietary medicines, producing as witnesses two expert analysts and a number of makers and proprietors of secret remedies.

THE DIFFERENT CLASSES OF PROPRIETARY REMEDIES.

34. Patent and proprietary medicines differ very widely in character. At one end of the scale is the valuable scientific preparation; at the other end is the mere vulgar swindle. Any useful consideration of them must therefore be preceded by some classification into distinct categories, as these may call for widely differing treatment in the public interest, corresponding to their differences of character. For the purpose of this Report we adopt the following classification, which is largely supported by the evidence of expert witnesses of high standing. In the first place we divide these remedies into two chief classes: (A) Non-secret and (B) Secret. That is, those of which the formula is published, and those of which the formula is not published.

Class A.—Non-Secret Remedies.

Group 1. *Proprietary preparations.*—This group consists of genuine drugs, originally produced synthetically, or extracted from crude compounds, by skilled chemists and tested by therapeutists, and manufactured (though under many names) in pharmacological laboratories. Familiar examples are aspirin, adrenaline, and urotropine. The processes of manufacture are patented, or the names are registered trade-marks.

Group 2. *Remedies owing their value to skilful combination.*—Examples of this group are various emulsions of cod-liver oil or petroleum, and mixtures of bismuth with pepsine. They contain no new drugs, but are only new combinations, depending for their palatable or assimilable qualities upon the skill with which they are compounded.

Group 3. *Non-secret drugs with secret excipients.*—These are known drugs with formula disclosed, mixed for purposes of convenient or elegant manufacture with minute quantities of medically inert substances, the nature of which is a trade secret. The most familiar example of this group is the large quantity of medicine sold in "tabloids," this trade name being the property of one firm.

It will be evident that unless some of the above drugs are such as should not be sold at all; unless it should

be thought desirable to forbid unfounded claims of efficacy in curing disease; or unless any restriction of the multiplication of trade names be recommended, there is nothing in the above Class calling for interference in the public interest. The second Class occupies a different position.

Class B.—Secret Remedies.

In consequence of the great variety of remedies of this class, it is difficult to give an adequate classification of them without entering into excessive detail. For practical purposes, however, they may be divided into three general groups.

Group 1. *Simple household remedies.*—This group consists of a number of household remedies, often originally manufactured from a doctor's family prescription, and undoubtedly beneficial for uncomplicated ailments. They have in most cases been sold for many years, and as their retail price is out of all proportion to their cost, large fortunes have often been amassed by their proprietors. Except for the fact that often the advertisements of them recommend their use for cases they cannot benefit, thus causing the purchaser to run the risk of serious injury by delay in securing proper medical treatment, there is little or nothing to criticise in their sale. We cannot, of course, give examples of these, as our remarks would at once be used for advertising purposes.

Group 2. *Dangerous remedies, and drugs for improper purposes.*—This is a small class of drugs which should not be sold at all, of which acetanilide is possibly an example; which should not be sold except on a doctor's prescription; or which should not be sold for the purpose for which they are offered—as, for example, an unsuitable drug as a general medicine for young children.

Group 3. *Fraudulent remedies.*—This is a large class, having an extensive sale, often at high prices, consisting of abortifacients, of alleged cures for cancer, consumption, diabetes, paralysis, locomotor ataxy, Bright's disease, lupus, fits, epilepsy, rupture (without operation or appliance), deafness, disease of the eye, syphilis, &c., together with electric belts, apparatus for supplying oxygen to the system (other than by inspiration), "ionised" waters and the like. The discovery of radium will probably add a number of remedies to this group. There should be little difficulty in identifying remedies of this class, and their treatment in the public interest need involve no doubt or hesitation. They are, and are known by their makers to be, cruel frauds; and the sale and advertisement of them should be prohibited under drastic penalties.

Group 4. *Remedies making grossly exaggerated claims.*—This is a final large class. Genuine simple remedies making exaggerated claims are included in Group 1, as the exaggeration in their case is usually of the nature of the "trade puff." Those we have in view in this group are remedies depending for their sale largely or wholly upon the extravagant promises they hold out to the purchaser. This, under the name of "misbranding," is now prohibited by law in the United States, and many cases came before us in which the advertisements of proprietary remedies in this country were refused admission into Australia. This group presents obviously great difficulties in drawing the line between claims which are merely "puffs" and claims which are fraudulent, but we regard it as beyond question that the public is defrauded on a large scale by promises which cannot possibly be fulfilled. As an example of the profits made by the sale of this class of remedies, George Taylor Fulford, the proprietor of "Dr. Williams' Pink Pills for Pale People," left a fortune of £1,111,000.

MEDICATED WINES.

35. In addition to the various classes of patent and proprietary remedies, our attention has also been forcibly called to the advertisement and sale of medicated wines, and weighty opinions have been quoted to us regarding their mischievous effects. The trade in these wines is a very extensive one. Messrs. Coleman & Co., the proprietors of "Wincarnis," have a capital of £250,000, employ between four and five hundred persons, and, as before stated, spend £50,000 a year in advertising. Mr. Henry James Hall, trading as Stephen Smith & Co., the proprietors of "Hall's Wine," has a capital of £175,000. The alcoholic content of these wines is very high. For purposes of comparison, the alcoholic strength of familiar wines may be taken to be as follows:—

	Per cent.		Per cent.
Claret	9	Sherry	18
Hock	10	Port	20
Champagne	10-15		

The alcoholic strength of well-known brands of medicated wines was stated to us as follows:—

	Per cent.		Per cent.
Bovril Wine	20	Spier's and Pond's Wine	17
Lemco Wine	17	Savar's Wine	23
*Wincarnis	19.6	Coleman's Coca Wine	16
Bendle's Wine	20	Hall's Wine	17.8
Glendinning's Wine	20.8	Vin Mariani	16
Ambrecht's Coca Wine	15	St. Raphael Tonic Wine	16

* The proprietor stated this percentage to be about 17 per cent. of absolute alcohol.

A number of other preparations contain a high percentage of alcohol, without bearing any suggestion whatever that they are alcoholic. For example:—

	Per cent.		Per cent.
Carnrick's Liquid Peptonoids	20	Carnaby	17
Panopeptone	20	Junora	11.9
Armour's Nutritive Elixir of Peptone	15	Vibrona	19
		Lydia E. Pinkham's Vegetable Compound	20

Thus, though we cannot take responsibility for the foregoing figures, it would appear that many of these wines and preparations are as alcoholic as the strongest wine, and most of the rest are about twice as intoxicating as ordinary claret. One wineglassful of a 20 per cent. wine or preparation contains three and a half teaspoonfuls of absolute alcohol; one wineglassful of "Wincarnis" three teaspoonfuls. The recommended dose of "Wincarnis" equals one wineglassful of whisky per day.

Some medicated wines claim to be nutritive because meat extract enters into their composition. The quantity of meat extract, however, is trifling, and in any case it is not nutritive. "Wincarnis," for instance, is declared to "give a strength that is lasting, because in each wineglassful there is a standard amount of nutriment," and is described as "the world's greatest tonic, restorative, blood-maker, and nerve food." Its proportion of meat extract is 1.2 per cent., or about one-twentieth of the nitrogenous (flesh-forming) constituents of lean beef-steak. An analysis made by the public analyst of the city of Bradford says: "It is so deficient in albumenoid nitrogen and phosphorus, essential constituents of nerves and flesh, that in these respects it is but very little superior to port wine itself." "Lemco Wine," again, contains only 0.6 per cent. of meat extract, but 12 per cent. of sugar. Alcohol, moreover, cannot contain meat extract in solution, and presumably any medical man desiring to administer meat extract would prefer to do so without mixing it with alcohol.

There can be no doubt that many persons acquire the "drink habit" by taking these wines and preparations, either knowing that they are alcoholic, since they can be purchased and consumed without giving rise to the charge of "drinking," or in ignorance that they are highly intoxicating liquors. The further charge is made that their drug content may lead to the "drug habit." "Hall's Coca Wine" is now called simply "Hall's Wine." It contains one grain of the

extractive principle of the coca leaf (which is mainly cocaine) in 26 fluid ounces, a sufficient amount, as stated by the proprietor, to cause sleep if two wineglassfuls are taken. It is recommended for children in these words: "For colds, coughs, and bronchial affections: children, a dessertspoonful three times daily." One "nutritive tonic wine" (Bugeaud's) is advertised as containing "cinchona (quinine) and cocoa." It contains no cocoa. The word is probably a misprint—perhaps accidental—for "coca." In some cases the proprietors of these wines offer to pay for the wine licence of retailers. A well-known firm of chemists, commenting upon this, wrote: "On our expressing surprise that they could do this, we were told that of course they would expect our orders for ordinary unmedicated wines, the demand for which always followed, in their experience, where the medicated kinds were introduced." It is stated that doctors' testimonials are secured by the offer of a free 2s. 6d. bottle for any poor person to whom the doctor may like to send it, on his returning a signed coupon. Thus Coleman and Company claim to have 6000 signatures of medical men in favour of "Wincarnis." The President of the British Medical Association gives this further explanation: "The profession has been educated up to a better standard about the giving of testimonials, but it was culpably lax some years ago."

EXAMPLES OF SECRET REMEDIES.

36. In order to show the character of a large class of secret remedies, and at the same time to exhibit the general justification of some of our recommendations, we think it desirable to give in detail a number of facts we have elicited in examination of witnesses. The following examples are taken almost at hazard, but they are types of innumerable old and new preparations advertised widely throughout the country, and they are constantly being added to. We would draw special attention to the fact that three of the remedies mentioned below (a, b, and i) are the property of witnesses not selected by ourselves, but put forward by the Proprietary Articles Section of the London Chamber of Commerce as representative of the trade in secret remedies.

(a) "Mother Seigel's Syrup."—This is one of the most familiar and widely sold secret remedies. The proprietors are A. J. White, Ltd. (Mr. White was an American, who died in 1899), of 35, Farringdon-road, London. When the present limited company was formed in 1897 with a capital of £1,000,000, the vendor's profit was £900,000. The capital has since been written down to £300,000. It employs 250 to 350 persons and pays from £30,000 to £40,000 per annum in wages, and a hundred million bottles are said to have been sold. It cannot be sold, unless smuggled, in Germany (where it is prohibited by name except on a doctor's prescription), France, Austria, or Italy.

For many years this preparation bore the statement that "an old woman, Mother Seigel, on her last legs with dyspepsia, was given up by her relatives and was allowed to wander in the lanes round her native village in Germany, and that one day she chewed a leaf of a herb only found in those parts, and found immediate relief." Your Committee arrived at the conclusion that every detail of this statement was an invention. There never was a Mother Seigel or this wonderful herb, and the entire story appears to be a fabrication.

This remedy is advertised as "a cure for impurities of the blood," "a cure for dyspepsia and liver complaints," and "a cure for anæmia," and it is described as "a highly concentrated, purely vegetable compound." The statement that it is "purely" vegetable was, we were told by the proprietors, "apparently put in by the advertisement writer without proper consideration." It is incorrect, as the preparation contains hydrochloric acid and borax. It is made up in batches of 200 gallons, and consists, the proprietors state, of a mixture of eleven vegetable substances,

and therefore, as previously explained, it cannot be exactly analysed.

We considered "Mother Seigel's Syrup" at great length, regarding it as in many respects a typical secret remedy. To the representative of the proprietors we put no fewer than 1607 questions, and we received much technical evidence concerning its contents from three analysts, and from the Government Chemist and his assistant. The analysis given in "Secret Remedies" was disputed by and on behalf of the proprietors, and was defended by the analyst put forward by the British Medical Association. We think it well, therefore, to give in full the following analysis made for us by the Government Chemist, as this also illustrates our remarks above upon the limits of analysis of preparations containing a number of vegetable extracts.

"The analysis of the sample gave the following results:—

	Per cent. by weight.
Water and volatile acid	57.5
Mineral matters (ash)	5.1
Reducing sugars (calculated as invert sugar) ..	16.2
Cane sugar	11.0
Organic solids other than sugar	10.2
	100.0

"1. *Organic Ingredients.*—The proportion of sugars in the sample represents about 40 per cent. of treacle. In addition to the sugars, the organic ingredients were found to include:—

Essential oil, having an odour of saffras ..	A small quantity.
Starch	do. do.
Acetic acid	0.66 per cent.
Capsicum, equivalent to about 1 per cent. of tincture of capsicum, B.P.	
Aloes	About 1 per cent.
Other vegetable extractive substances (after deducting 1.4 per cent. of extractives due to treacle)	7.8 per cent.

"We have not found it practicable to separate characteristic constituents, or to obtain characteristic reactions, which would serve to identify definitely any organic ingredients of the mixture other than those mentioned above.

"2. *Mineral Ingredients.*—These consisted of bora with small quantities of chlorides, sulphates and phosphates, such as occur in the ashes of vegetable substances.

Total boric acid ..	2.12 per cent. (equivalent to 3.26 per cent. of crystallised borax).
Total chlorides ..	1.51 per cent. (calculated as hydrogen chloride).

"3. *Acids.*—The volatile acid consisted mainly of acetic acid, with a little boric acid. The total free acid of the sample in terms of hydrochloric acid is 1.12 per cent., equivalent to 10.6 per cent. of the Pharmacopœia 'diluted hydrochloric acid.'

"The proportion of free acid, other than acetic acid, would correspond with 0.72 per cent. of hydrochloric acid, equivalent to 6.8 per cent. of the 'diluted hydrochloric acid' of the Pharmacopœia. Very little of this hydrochloric acid, however, would be actually present in the 'free' condition.

C. SIMMONDS.

JAMES J. DOBBIE.

"Government Laboratory, 21st December, 1912."

This official analysis and that of the analyst for the proprietors practically agree in the percentage of treacle (40 per cent. and 42 per cent.) and of vegetable extractive substances (7.8 per cent. and 8.42 per cent.). From the foregoing the fact emerges that 100,000,000 bottles of an American mixture, originally recommended by an elaborate falsehood, and containing—apart from about 10 per cent. of vegetable extracts, including aloes and capsicum, of whose names, therapeutic virtues, and money values we are ignorant—50 per cent. of water and 40 per cent. of treacle, have been sold at the retail price of 2s. 6d. for three fluid ounces.

(b) "*Daisy*" Powders.—These are the property of "Daisy, Limited, Leeds," a company with a capital of £15,000, employing about 40 persons. As at first sold, this medicine, which was originated in this form in 1893 by an unqualified retail druggist, was known as "Daisy Headache Powder," and contained 5 grains of acetanilide. The Board of Inland Revenue decided that this—which was exempt from stamp duty as a "pure drug"—could only be sold by pharmacists or persons holding a Patent Medicine licence, and many of the retailers of the powders were in too small a way of business to pay 5s. annually for this, even although the proprietors offered to pay half the cost. Therefore a second identical powder was put on the market, bearing the words "Head Powder," and "Daisy, Limited, Leeds," the label designed to lead the public to think it the same as the original powder. But the Board, after a long correspondence (which was shown to us), insisted that the packets bearing different names must contain different substances. Therefore a "Daisy Headache Powder" still contains 5 grains of acetanilide, but a "Head Powder" of "Daisy, Limited, Leeds," contains 8 grains of phenacetin.

The assets of this Company consist chiefly of the goodwill in the trade name "Daisy" (they informed us that they had also registered the word "Buttercup"), and their business consists in buying acetanilide and phenacetin by the ton, these costing respectively 9d. and 2s. 11d. a pound, and supplying them in 5 and 8 grain packets to retail at a penny apiece. When asked by our medical colleague whether headache might not be a warning symptom of serious diseases, and that therefore merely to remove the symptom might be a dangerous step, the proprietor replied: "I say headache is a pain in the head, and I say that a 'Daisy' powder will remove the ache." The official dose is 1 to 3 grains, and the Codex adds: "Doses of 5 to 10 grains are sometimes ordered, but may cause alarming symptoms." Prof. Dixon, M.D., F.R.S., one of the highest authorities upon pharmacology, informed us that acetanilide is a dangerous drug, and he went so far as to say that it "ought never to be given under any circumstances."

(c) "*Fenning's Fever Curer.*"—This is advertised in the following terms: "The celebrated Remedy for the Prevention and Cure of Typhus, or Low Fever, Cholera, Diphtheria, Scarlet Fever, Fluxes, Yellow Fever, Influenza, Black Fever, Dysentery, Windy Spasms, Sore Throats, Gripping Pains, Low Spirits, Diarrhoea, Small Pox, &c. Sore throats cured with one dose. Scarlet or Typhus Fever prevented or cured. Bowel complaints cured with one dose. Typhus or Low Fever cured with two doses. Diphtheria cured with three doses. Scarlet Fever cured with three doses. Cholera cured with five doses. Influenza cured with six doses." The Government Chemist informed us that this consisted of a dilute solution of nitric acid, flavoured with peppermint. It is sold at 1s. 1½d. for about 8 fluid ounces. The estimated cost of the ingredients is ½d.

(d) "*Antipon.*"—"One of the most valuable discoveries in modern therapeutics, solving once and for all the vexed question of the radical cure of obesity without harmful after-effects." A solution of citric acid in water, which we were informed would be without medical effect upon corpulency.

(e) "*Vitadatio.*"—"Will cure the most severe cases of cancerous growths, tuberculosis, consumption, heart trouble, and tumours." We sent this to the Government Chemist. It is apparently a decoction of bitter herbs, containing only 1.48 per cent. of total solids, and no alkaloids or resins.

(f) "*Veno's Lightning Cough Cure.*"—"If it fails, no other medicine will ever succeed." According to the statement of the analyst of the British Medical Association, this contains about 8 per cent. of glycerine, with small quantities of alcohol, chloroform, and resin.

(g) "*Mer-syren*."—"Composed of the active principles of certain rare plants which flourish in the valleys situated on the southern slopes of the Himalaya, between the immense gorge separating Nepal from Bhutan on the East and Almorah on the North-West." Recommended by "Dr. Pearson, late principal Medical Officer, North Bhangulpore, India." No place named Bhangulpore is mentioned in the Imperial Gazetteer of India. A cure for "dropsy, insanity, small-pox, angina pectoris, diphtheria, erysipelas," &c. No substance but potato starch could be detected by analysis.

(h) "*Phosferine*."—"The greatest of all tonics." A weak solution of quinine in phosphoric acid. Prof. Dixon informed us that this contains no phosphorus which can have a therapeutical effect, and that any other acid to make a solution of quinine would do equally well.

(i) "*Steedman's Soothing Powders*."—These contain, according to the Government Chemist's report, 27.1 per cent. of calomel. The directions for use for children say: "One may be taken for three or four nights successively at any time when the child complains of being poorly." The powders vary in weight, and a child may thus get one grain of calomel for several nights in succession. The toxicologist put forward as a witness by the proprietors admitted that "that is a somewhat tall order." In connexion with this remedy we learned that the pamphlet entitled "*Hints to Mothers*," accompanying it, and professing to be "by an M.D. London" recommending these powders on every page, was revised by a reputable London doctor, at the request of an advertising agent; that the references to these powders were subsequently inserted without the doctor's knowledge; and that "M.D. London" only meant a doctor living in London, and not, as would naturally be inferred, an M.D. of the University of London. It was not clear to us whether the proprietors and the publishers of this booklet were both responsible for the misstatement.

(j) "*Matrozone*."—Made in a northern seaport, and said to have a large sale in the North of England. The package contains two bottles, each holding one fluid ounce, and sells for 5s. 6d. The accompanying booklet says: "This treatment is the result of the patient investigation of a Minister of Religion. . . . When a young man pursuing his studies with a view to qualifying for the Medical Profession he was profoundly impressed by the death of a young wife," &c. Its claim is as follows:—"Matrozone Promotes Natural, Rapid, and Easy Confinement. Ensures Healthy, Beautiful, and Bright Children." One bottle contained 68.9 per cent. and the other 60.3 per cent. of alcohol, with total solid matter too small to be weighed, such as might come from diluting the alcohol with tap-water, with no trace of any alkaloid.

(k) "*Burgess's Lion Ointment*."—Advertised to cure tuberculous tumours, piles, fistulas, rheumatism, gout, sciatica, &c. "They are vegetable preparations." The chief ingredient is lead oleate (diachylon plaster), and no vegetable extracts or active principles are present.

(l) "Dearborn, Limited," a company founded almost without capital, with one director and two shareholders, employs six persons—a secretary, a typist, two bookkeepers, and two packers. Its business consists in inventing fancy names for preparations (see Par. 38), buying these from well-known manufacturers, labelled with these invented names, and selling them as remedies for short hair, freckles, liver spots, &c., by means of correspondence passing between fictitious persons and real or fictitious correspondents, inserted as, but not marked as, advertisements in popular magazines. Sometimes these are followed by an avowed advertisement, to suggest that what precedes is not an advertisement.

(m) "*No-Germo*."—This was put upon the market, with full-page advertisements in the press, three

months ago. It was announced in the following terms: "The wonderful remedy invented by Gertrude, Lady Decies has achieved a well-deserved popularity by its success in curing the most stubborn Colds, Hay Fever and Influenza, Nettle-rash, Eczema, and other Skin diseases. It acts as a soporific in cases of Insomnia; it affords great relief in Asthma: it is a prompt and certain cure for Stings of Wasps, Mosquitoes, and other insects. It is very easy to use and perfectly safe." We requested the Government Chemist to furnish us with an analysis of this, but he felt unable to do so, as its composition had been divulged to him in confidence by the manufacturers in connexion with action by the Customs and Excise. He therefore nominated, with the sanction of the Treasury, Mr. E. J. Bevan, F.I.C., County Analyst of Middlesex, and the latter has furnished us with the following report:—

"*No-Germo*" consists of an alcoholic solution containing camphor, ammonia and oil of cinnamon.

"It is conceivable, but unlikely, that there may be traces of other bodies, but I have not been able to discover them. The liquid is slightly yellow, more so than could be accounted for by the amount of oil of cinnamon present, but the difference in colour is most probably due to the prolonged action of the ammonia on the oil of cinnamon.

"Possibly the ammonia is present in the form of sal-volatile, but I am unable to say definitely.

"Beside the sample sent officially, I have examined, in more or less detail, eight other samples that I purchased at various chemists' shops. There is a very large variation in the composition. For example, the alcoholic strength varies from 51.1 per cent. to 64.8 per cent., and there are similar variations in the oil of cinnamon, the camphor and the ammonia.

"The average composition is set out below:—

Alcohol	..	..	..	..	58.3 per cent.
Oil of cinnamon	..	..	..	..	0.5 "
Camphor	..	..	..	..	1.03 "
Ammonia	..	..	..	..	0.33 "

"The approximate cost of one bottle, selling at 2s. 3d., is 3.64 pence, say 3½d."

Of the remedies discussed in this paragraph no person connected with those lettered c, d, e, f, g, h, j, k, and m took advantage of our general invitation to give evidence before us. We have, therefore, had no opportunity of hearing what they had to say in justification of their methods, or in criticism of the statements made to us by other witnesses in reference to the articles sold by them. Persons interested in the remedies lettered a, b, and i appeared before us, and it is only fair to state that they strongly contested the accuracy of the analyses furnished to us of the constituents of their remedies. In dealing with this latter group at some length we have no intention of suggesting that these are exceptionally bad cases. The fact these persons gave evidence creates a presumption that they were better able to face examination of their business and their goods than many others manufacturing secret remedies.

EXAMPLES OF FRAUDULENT CLAIMS.

37. The following are a few examples, which could be multiplied almost indefinitely, of fraudulent claims:—

"The best remedy for consumption." (*Congreve's Elixir*.)

"Cures Bright's disease." (*Munyon's Kidney Cure*, consisting of sugar only.)

"It never fails to cure cancerous ulcers, syphilis, piles, rheumatism, gout, dropsy." (*Clarke's Blood Mixture*.)

"Bright's disease, stone in the bladder, dropsy, eczema, scrofula . . . can be speedily cured." (*Warner's Safe Cure*.)

"The absolute specific for all, or some, of their phases" of "syphilis and every form of venereal disease." (*Wallace's Specific*.)

"Applied freely will cure lumbago or sciatica in one night." (*Levasco*.)

"Cured not only rheumatism, but anæmia, eczema, sciatica, St. Vitus's dance, spinal weakness, &c." (*Pink Pills for Pale People*. These contain ferrous sulphate, and are one of the many variations of Blaud's pill—the *pilula ferri* of the British Pharmacopœia.)

"The remarkable curative influence exercised in cases of Bright's disease." (*Beecham's Pills*. This statement was made for many years, but was dropped a few years ago.)

"It will be sufficient to offer a few general remarks, and to indicate the method of cure [of syphilis], which is, beyond all, the question of supreme importance. Let it never be forgotten that even a slight delay in dealing with diseases of this type may be terribly fruitful of future trouble. In the first place, the advice of a properly qualified medical man is necessary, whatever the character of the disease, or whether it be hereditary or acquired. But the process of eradicating the poison from the system will be materially assisted by the aid of a perfectly safe, but reliable, searching, cleansing, purgative medicine; and nothing better for that purpose can be used than Beecham's Pills. They should be taken immediately and continued for a considerable time after the cure is apparently complete." (*Beecham's Pills*. A part of this statement was characterised to us by Dr. W. Perrin Norris, formerly Director of Quarantine and practically Director of Public Health for the Australian Commonwealth, as "from our standpoint, one of the more serious, if not criminal, pieces of printed matter I have ever seen.")

INVENTED NAMES OF DRUGS.

38. A new and ingenious method of defrauding the public by the sale of secret remedies has recently been devised. This consists of inserting a "reader" advertisement—without the suffix "Advt." whenever the newspaper or magazine will consent to omit this—recommending for an ailment or a physical blemish a simple prescription containing one drug or preparation bearing a fancy name, "which any chemist will supply." This is an ordinary drug put up as a proprietary remedy under a fancy name, and sold, of course, at a fancy price. Sometimes these advertisements take the form of "Answers to Correspondents," or are given under the authority of a fictitious person, "Madame Lucie Robert," for instance. Examples of such fancy names are "pure colourless kalamax," "salith leaves," "stallax," "pheminol," "pergol," "pure bisurated magnesia," "boranium," "karox," "pilentia soap," "jettaline," "allacite of orange blossom," "tennaline," "carmarole," &c. These names are all invented words and should properly be printed with a capital initial letter, the proprietors having the exclusive right to their use as trade names. They are, however, printed in these disguised advertisements without capitals, to deceive the public into the belief that they are not proprietary articles, but are familiar drugs purchasable in small quantities at ordinary prices, whereas, in fact, they are only sold in a considerable quantity at a fancy price.

CHANGES IN NAME OR COMPOSITION OF REMEDIES.

39. It is not uncommon for the composition of a secret remedy to be altered without any change in the name. "Anti-kamnia," as we have said, was acetanilide in America, and is now phenacetin, and "Daisy" powders were similarly changed. "Powell's Balsam of Aniseed" was repeatedly proved in courts of law to contain morphine. It now contains none. The same is true of "Mrs. Winslow's Soothing Syrup." The formula of "Pond's Arthritic" was said to be altered by the addition of potassium

bromide and salicylic acid. The powders in one packet of "Steedman's Powders" varied in weight from 1.9 to 4.5 grains. Sir Joseph Beecham informed us that "Beecham's Cough Pills" at one time contained morphia, as that was considered to be a necessary medicinal ingredient; that when the law compelled the word "Poison" to be put on the wrapper of preparations containing morphia, the morphia was taken out of the pills; then so small a quantity was put in again that it was "comparatively innocuous or perfectly innocuous," and therefore did not need to be labelled "Poison." That is, a potent drug was put in this remedy, taken out, and put in again, without regard to its medicinal effect, but solely because of the legal conditions under which it could or could not be sold.

CURE OF SYMPTOMS.

40. We have had occasion to remark upon the possible evil effects of causing the disappearance of a symptom, which may be nature's danger-signal, without effecting in any way the disease which causes it. In this connexion we may also point out that remedies offered for the same ailment—a cough, for instance—may affect it for good or for evil according to its nature and cause. The secret remedy naturally takes no account of this. For example, "Owbridge's Lung Tonic" is an expectorant mixture, a mixture to increase coughing, its principal ingredient being ipecacuanha. Whereas "Keating's Cough Lozenges," or "Beecham's Cough Pills," are the opposite kind of remedy, containing opium or morphia, the object being to stop the cough. A man whose chest is full of fluid needs to have his cough facilitated. A man with a varicose vein on his uvula needs to have his useless and exhausting cough stopped. Proprietary medicines make no attempt to distinguish between these two common types. Secret remedies, too, are constantly recommended for different ailments having a superficial resemblance, but medically considered, totally diverse. For example, "Beecham's Cough Pills" are recommended as "a safe and simple remedy" for both asthma and bronchial affections—asthma being a nervous disease, while bronchial affections are inflammation of mucous membranes. These examples, which could be multiplied, illustrate the danger of this kind of ignorant self-medication, upon which medical witnesses laid much emphasis.

"CURES" FOR FITS.

41. Advertisements by private persons offering cures for fits are familiar. With the help of the Chief Constable of Cheshire and the Government Chemist we investigated one of these. The advertisement read: "Fits.—Clergyman offers prescription for 1s. 1d.; never fails.—J. S., Grasmere House, Winsford, Cheshire." Three different sets of initials were used at different times. Application brought a prescription for "koronium bromide," and a recommendation to procure it from "the actual manufacturers, Messrs. Whitby & Co., Chemical Manufacturers, Winsford, Cheshire." This was sold at 4s. 6d. for 4 ounces. We procured some, and—"koronium bromide" being, of course, an invented name—the Government Chemist informed us that it was the well-known drug strontium bromide, often prescribed for epilepsy, and purchasable at rates varying from 2s. to 3s. 8d. a pound. Police inquiries then showed that the advertiser was Harold Cuthbert Whitby, trading in a lock-up shop at Winsford, as "Whitby & Co., Chemists, Opticians and Wine Merchants."

THE TRADE IN ABORTIFACIENTS.

42. The trade in abortifacients presents one of the most deplorable aspects of the secret remedy trade. Innumerable remedies for "female irregularities" are advertised. A few of these are poisonous and have

caused death, whilst most of them are wholly inactive for the purpose for which they are sold. Indeed, it cannot be too widely realised that no drug is known which can force the womb to expel its contents, and that nothing can endanger the life of an unborn child except by endangering in an equal degree the life of the mother. But a substance of the latter class is unfortunately widely sold and used in certain parts of the country as an abortifacient. This is "diachylon plaster," the *emplastrum plumbi* of the Pharmacopœia, a preparation of lead oleate, containing 28.9 per cent. of oxide of lead, supposed to be a mild astringent for application to inflamed surfaces. One medical witness expressed to us the opinion that for all practical purposes it is perfectly useless. But it is undoubtedly widely taken as a supposed abortifacient in the form of pills like "Mrs. Seegrave's Pills," or merely a bit of the plaster rolled up and swallowed.

Many deaths from the use of this substance for this purpose were reported to us. It can, of course, only produce abortion by producing lead poisoning, from which insanity, blindness, paralysis and death have resulted. The Pharmaceutical Society have for years vainly urged its inclusion in the Schedule of Poisons. The question of the total prohibition of its sale should be considered by the competent authorities.

Blackmail is a natural result of the sale of abortifacients. In 1898 two brothers named Chrimes were sentenced to penal servitude for demanding, under threats of exposure, two guineas from women who had purchased their drugs. The police intercepted in a short time no fewer than 600 letters, each containing two guineas.

Even simple aperient pills from reputable makers are recommended in language suggesting that they are efficacious for this particular purpose. In the instructions headed "Advice to Females" accompanying "Beecham's Pills," women suffering from "any unusual delay" are recommended to take five pills a day. The proprietor admitted in evidence that the most common cause of such delay is pregnancy.

"CURES" FOR CONSUMPTION.

43. Amongst fraudulent secret remedies the alleged cures for tuberculosis are perhaps the worst of all. Sufferers from this disease are, as is well known, peculiarly credulous of promises of help, and the "consumption quack" takes skilful and unscrupulous advantage of their pathetic hopes. Many secret remedies for consumption have been put upon the market, usually at high prices. For example, an American firm known as the Derk P. Yonkerman Company advertised for some years a remedy called "Tuberculozyne," Yonkerman himself being a Michigan veterinary surgeon. A month's treatment by this remedy cost £2 10s. The advertisement offered a book entitled "Consumption and How it Can be Quickly Cured," of which the following paragraph is typical:—

"After researches lasting for nearly twenty years, the persistent efforts of Dr. Derk P. Yonkerman have been crowned with success, for his Tuberculozyne treatment has already been proved in hundreds of cases to be a specific of almost miraculous curative power. Its healing virtues have been demonstrated in not only the early stages of consumption, but in far advanced and seemingly hopeless cases as well."

The inventor announced that he had "discovered certain salts of copper of remarkable therapeutic value. The consumption germs cannot live in the presence of copper, and as the Tuberculozyne treatment introduces copper into the blood the consumption germs cannot live." The remedy was contained in two bottles. Analysis showed one bottle to contain 18 parts of glycerine, with water and brown sugar, and the other 3.4 parts of potassium bromide, 12 parts of glycerine and a trace of capsicum, the whole

coloured by cochineal. The preparation probably originally contained sulphate of copper when it was prepared in America, but we were informed that such was the chemical knowledge of Yonkerman that he sent his mixture to England in iron drums, the whole of the copper being deposited upon the iron during transport. The importation of "Tuberculozyne" into the Australian Commonwealth is prohibited. We would draw attention to the fact that this remedy is one of a peculiarly bad class, which are not advertised in the press or sold through the respectable retail trade, but constitute what is known as "mail order business."

Another well-known "consumption curer" is a man named C. H. Stevens, who has been denounced in *Truth* for nearly ten years, and against whom an action was brought by a widow in the Basingstoke County Court on July 27th, 1910, to enforce payment of a "guarantee bond" containing an undertaking that money paid for the remedy would be refunded if no cure were effected. The Judge found for the widow, refused leave to appeal, and described the transaction as "an intentional and well-considered fraud."

Our attention was called to Stevens by a letter addressed to the Chairman stating that the writer had seen in a newspaper a report of our proceedings, that he was suffering from tuberculosis and was taking a patent medicine from a London firm who guaranteed a cure, of the name of C. H. Stevens, of Wimbledon, regarding which he asked the opinion and advice of your Committee. After some correspondence this gentleman consented in the public interest to give evidence before us, but on the condition that his name should not be published. He appears, therefore, in the Report of our Proceedings of July 16th, 1912, under the name of Mr. A. His correspondence with Stevens, which he placed in our hands, was, as might be expected, a series of complaints that he was getting no better but rather worse, with assurances from Stevens that persistence in the use of the remedy would certainly effect a cure. At last Mr. A requested the return of the five guineas paid, in accordance with Stevens's guarantee, and finally, under the threat of legal proceedings and after Mr. A had appeared before us, Stevens returned the money. We submitted two bottles of the remedy supplied by Stevens to the Government Chemist, who gave us the following analysis:—

	Sample first bottle. Per cent.	Sample last bottle. Per cent.
Proof spirit	19.5	19.5
Solid matter	2.8	3.4
Mineral substance (ash) ..	0.2	0.2
Glycerol (approximately)	10.7	17.8

"No alkaloids or resins were found. The solid matter corresponds with the colouring and extractive substances of an ordinary wine. The samples are therefore essentially mixtures of wine and glycerol." (Glycerol is glycerine.)

It is instructive as illustrating the credulity of the public, that Mr. A, although an intelligent man, believed that Stevens's lithographed letters were written by Stevens's own hand with reference to his particular case, and that in spite of our efforts to enlighten him, he was obviously still impressed when he left us by Stevens's "challenge" to the Brompton Hospital for Consumptives. This was a request from Stevens to the authorities of the hospital to inoculate him with the worst form of tuberculosis, on the condition that when he cured himself by his own remedies the hospital should adopt his treatment for the cure of consumption. An eminent specialist, Dr. Hector Mackenzie, was good enough to examine and advise Mr. A at our request, without professional charge, and he informed us that in his opinion excavation of the lungs had taken place or extended during the time that Mr. A was taking Stevens's remedies. Stevens was inserting full-page advertisements of his consumption cure in London daily papers last year. We may add that Stevens has

recently brought an action for libel against the British Medical Association for statements made regarding his remedy in "Secret Remedies." The defendants pleaded justification, and the jury found for the defendants.

FICTITIOUS NAMES.

44. It is a common practice of vendors of secret remedies to recommend them by the name of a fictitious person. We have already mentioned "Mother Seigel" and "Madame Lucie Robert." Another example is "Mrs. Johnson's Gripe Relief," with which Mrs. Johnson had nothing to do. Another is "Roulet injection" for gonorrhœa, guaranteed by the facsimile signature of "Dr. Roulet," an imaginary person. Other fictitious names that have come to our notice are "Mademoiselle Florence Gauthier," "Mademoiselle Marcelle Rouvier," "Mildred St. Aubyn," "Mademoiselle Agnes Deprés," "Mademoiselle Marguerite Fournier," and "Dr. Duclaud."

PRACTICES OF SECRET REMEDY VENDORS.

45. The most disreputable class of proprietors of secret remedies trade under many aliases. As soon as one name becomes notorious, or when they have exhausted the credulity of the public for one remedy, they assume another name. Thus Crippen, the murderer, "aural surgeon to the Drouet Institute," was also M. Frankel. Elmer Shirley, who is still advertising extensively, has been Keith Harvey, Edward Meyer, the "Sanalak Institute," Marr, and Erasmus Coleman. An American named Skinner was successively Scott, Symond's London Stores, Professor Dana, Professor Pollock, and Horatio Carter. Nelson Lloyd, an Englishman who sold a "fat cure," was in reality an advertising agent named Derry. Two Americans, Virgil P. Neale and Thomas Adkin, were the Cartilage Company, advertising to increase height; as Harriet Meta they sold a "wrinkle eradicator"; as Kathryn B. Firmin, of the Roman Solvene Laboratory, they undertook to remove superfluous hair; and as Everett Wood they offered to make hair grow on bald heads.

46. The wiles of some vendors of secret remedies almost pass belief. Evidence was given to us in private to the effect that an agent of a "kidney cure" went from door to door in the artisan quarters of a northern town, stating that many people were in the first stages of kidney disease without suspecting the fact, but that a sure test was to take a pill which he left with them. If the urine became blue, he explained, that was a proof of kidney disease, which could certainly be cured by taking So-and-So's remedy. The pill contained a blue aniline dye, which of course produced immediately the result mentioned. The widespread alarm caused by this abominable trick may easily be imagined. We were informed that there exist to-day agencies, one in Leeds, which advertises frequently, and one or two in America, selling lists of names of sufferers from various diseases at so much per thousand. That is, a person about to put on the market a "consumption cure" or a "rupture cure," or a "cancer cure," can buy a list of a thousand persons suffering from tuberculosis or rupture or cancer, these lists being the names of people who have at some time answered advertisements regarding these diseases, and whose names and addresses thus possess a money value.

THE MEDICAL PROFESSION AND SECRET REMEDIES.

47. So far as we have been able to discover, no scientific chemist and no qualified medical man, with rare exceptions, is connected with or employed in the manufacture of secret remedies such as those we have placed in class B. And we have failed to find that any new drug, or new discovery of a method of compounding known drugs, has been placed at the service

of the public as one of that class of secret remedies. We have learned, however, to our great surprise, that persons of influential social position and small means will sell the use of their names to advertise secret remedies; that large sums of money are expended in canvassing medical men; that many medical men give testimonials (with the use of their medical qualifications but without the use of their names) to proprietary and secret remedies—and allow themselves to be made, as a medical man declared in a public address, "the catspaw and fool of the fraternity of the secret remedy"; and that there are medical men who prescribe to their patients remedies of this class of whose composition they are themselves largely ignorant. We had evidence in two cases of medical men acting as directors of companies manufacturing secret remedies.

THE PATENT MEDICINE STAMP AS AN ADVERTISEMENT.

48. We find that the Patent Medicine Stamp is not infrequently used as an advertisement. For example: "Therapion appears on Government Stamp, affixed to every package by His Majesty's Hon. Commissioners, and without which it is a forgery." And at the head of the booklet sent out by the proprietors of this remedy appears the words: "Protected by His Majesty's Hon. Commissioners," with the Royal Arms. Again: "To prevent spurious imitation of this excellent medicine. On the 24th of May, 1839, Her Majesty's Honourable Commissioners of Stamps ordered the name of 'John Steedman, Chemist,' to be engraved on the Government Stamp affixed to each packet, without which none after that date can be genuine." This was altered three years ago. Again: "To prevent fraud, His Majesty's Commissioners of Inland Revenue have ordered the words 'Lincoln and Midland Counties Drug Company, Lincoln, England,' to be printed in white letters on a red ground on the Government Stamp which is affixed over the cork of each bottle, and to imitate which is a felony. Please note that these words are engraved in the stamp, and the words 'Clarke's World-Famed Blood Mixture' are blown in the bottle." Again: "Caution. The public are requested to notice that the words 'Beecham's Pills, St. Helens,' are engraved on the Government Stamp affixed to every box of pills." Again: "Mrs. Johnson having disposed of the recipe and property in the American Soothing Syrup to Messrs. Barclay and Sons, begs to refer the Public to the Government Stamp with their name thereon as a security to purchasers." The object of these statements is obviously to cause the purchaser to think that the stamp implies some kind of guarantee of value of the remedy, although in recent years the stamp has borne the words: "This stamp implies no Government guarantee." The Inland Revenue authorities print the vendor's name on the stamp for a consideration of £8.

FRAUDULENT APPLIANCES.

49. Much fraud is also successfully practised by the advertisement and sale of appliances as alleged cures for many ailments. Electric belts and pads are a familiar form of these. Macaura's "Vibrator" was a clumsy method, at an exorbitant price, of applying mechanical massage, by which a little good might be done in a few cases and much harm in many cases. Artificial ear-drums of indiarubber, occasionally used by aurists, are sold by manufacturers at 1s. and 2s., but by quacks at from one to two guineas the pair, and often cause positive and serious injury. Appliances alleged to supply oxygen (otherwise than by inspiration), such as the "Oxydonor" and "Oxygenator," are of course deliberate swindles, for the makers cannot be supposed to be as ignorant of chemistry and therapy as their victims.

50. Lest it may be thought that the foregoing examples and remarks place even the worst class of

secret remedies in too unfavourable a light, we desire to call attention to a single answer of one witness regarding this trade in general. This was the chief witness put forward by the Proprietary Section of the London Chamber of Commerce on behalf of the trade, Mr. John Charles Umney, managing director of Messrs. Wright, Layman, and Umney, Ltd., an important firm of medicine proprietors and manufacturers of proprietary articles. In addition to this position, his personal qualifications include Pharmaceutical Chemist by examination, Fellow of the Chemical Society, Fellow of the Society of Public Analysts, Adviser in Pharmacy to the Local Government Board of Ireland, Technical Referee on Essential Oils to the Imperial Institute, Past President of the Wholesale Druggists' Association, first President of the Proprietary Articles Section of the London Chamber of Commerce, &c. And the question and answer were as follows:—

Chairman: Do you think, in view of your own position and attainments, and your business in these things, to which I have alluded, as to which you are put forward as a witness on behalf of the whole trade, that so far as a large part of the patent medicine trade is concerned you are a fair representative of it?

Witness: I hope I am not.

51. It will probably now be learned without surprise that witnesses of unquestionable authority have assured us that grave evils, urgently requiring remedy, arise from the present sale and advertisement of secret remedies. We may quote the following as examples. As regards diseases arising from sexual intercourse, Dr. Reginald Edward Cross, M.R.C.S., L.R.C.P.: "A very grave and widespread evil, urgently demanding legislative action." As regards aural diseases, Mr. P. Macleod Yearsley, F.R.C.S.: "A widespread and grave evil, which I most decidedly believe requires legislative treatment." Regarding dangerous drugs, Professor A. R. Cushny, M.D., F.R.S., Professor of Pharmacology at University College: "There is urgent need of new legislation." As regards diseases of the skin, Dr. Arthur Whitfield, M.D., F.R.C.P., Physician to the Skin Department, and Professor of Dermatology in King's College Hospital: "The harm done is appalling. . . . There is an urgent demand for legislation." As regards the sale of proprietary and secret remedies in general, Professor Walter Ernest Dixon, M.D., B.Sc., F.R.S.: "The existing law is greatly in need of amendment in the public interest." And on the general question a witness of a wholly different character, Mr. G. Sidney Paternoster, assistant editor of *Truth*, who gave us interesting and valuable evidence from the experience of that journal in pursuing for many years the vendors of fraudulent secret remedies: "There is an enormous evil, which calls for alteration of the law to meet it. . . . There is absolutely no question about it, the public is defrauded of millions in the course of a year, and purely by false statements."

REQUIREMENTS OF AUSTRALIAN LAW.

52. We have already spoken (*see* Par. 6 (1) of the law of the Commonwealth of Australia, as it affects the importation of proprietary and secret remedies. Some striking instances of the requirements of this law came before us in evidence, of which the following will be sufficiently illustrative.

The omission of this statement was required from the circular accompanying "Steedman's Soothing Powders":—

"Thus the commencement of hydrocephalus, tabes mesenterica, rickets, and other morbid affections may not infrequently be traced to the period of teething."

The same firm was required to print in capital letters on the label:—

"One powder only and no more."

And they were also required to state on the label:—

"The contents of this package include 27 per cent. of calomel."

In the circular accompanying "Beecham's Pills," when reference is made to kidney troubles, for the statement:—

"Beecham's Pills will probably be the only medicine required to achieve the desired result,"

the following was required to be substituted:—

"and no other aperient medicine is likely to be required than Beecham's Pills."

And the same proprietor was required to omit the statement regarding "Beecham's Cough Pills." "The cough pills do not contain any injurious ingredient," and the whole of the passage sent out with "Beecham's Pills" regarding "Secret Maladies."

On the label of "Woodward's Gripe Water" this statement occurs:—

"Celebrated Gripe Water, or Infants' Preservative" for the disorders of children—viz., convulsions, gripes, acidity, flatulency, whooping-cough, and the distressing complaints incidental to children cutting their teeth, allaying the pain, giving instant relief, and rendering this crisis perfectly mild and free from danger."

This was required to be reduced to the following:—

"For the relief of the simple and familiar ailments of infants and young children, especially during the period of teething."

The following sentences and names are examples of what under the Commonwealth law are regarded as "false trade descriptions," and are therefore prohibited:—

"Will cure any case of scrofula."

"Will prevent the return of cancer."

"An unparalleled remedy."

"It never fails."

"Surpasses anything ever discovered."

"The safest remedy in diphtheria."

"For all kinds of fevers."

"Cures any old disease lurking about the system."

"There is nothing in the world so good for you as

"Lightning Cough Cure."

"Skin Food."

Synthetic preparations bearing names indicating or suggesting a natural origin or base must have the word "artificial" added. For example, "Balm of Figs," "Fruit Pills," and "Sugar of Milk Pilules."

Fanciful names, like "August Flower," "Dutch Drops," "Orange Blossom," "Asiatic Drops," are not accepted unless supplemented by a description of the nature of the preparation or the maladies it is intended to cure.

Certain drugs, if present in a medicine, must be mentioned on the label and the quantity specified. These are such as the bromides, iodides, chloral, cantharides, phenacetin, &c.

The importation of articles and remedies may be totally prohibited. Among these have been the "Oxygenator," the "Oxydonor," and "Tuberculozyne."

Finally, "trailer" advertisements—that is, printed matter enclosed with one remedy and recommending another; advertisements recommending the regular use of a remedy, as for instance, "One of our pills taken twice a week will maintain you in regular functional activity"; and invitations to correspond, are forbidden.

The foregoing examples will suffice to show how the Commonwealth authorities carry out their aim—namely, the "application of common sense and common medical knowledge, with a view to the protection of the necessarily more or less ignorant public."

"EXHIBITION OF FORMULA."

53. It has been strongly urged upon us, chiefly by witnesses representing the medical profession, that every remedy sold should by law be compelled to bear a label stating its exact composition. This is what

is meant by "exhibition of formula," and witnesses advocating it came to us convinced that this simple change in the law would secure adequate protection of the public against injury and fraud. We have given long and careful consideration to this proposal, and we find ourselves unable to recommend it. In the first place, it would beyond question inflict a grave hardship, sometimes amounting to ruin, upon proprietors of secret remedies, or the loss of their investments upon shareholders in limited companies. Any long-established remedy in the lawful advertising and sale of which very large sums have been spent would immediately be faced upon the market by a score of preparations advertised as made from the same formula and sold at a much lower price. An example was given to us of a remedy the proprietary rights of which were immediately destroyed by a disclosure of its formula. The above would not, we are aware, be a conclusive argument against this proposal if its adoption would really protect the public against danger and fraud. We are convinced, however, that such would not be the case. Any benefit resulting from exhibition of formula must obviously depend for its efficacy upon the intelligence and education of the intending purchaser. It could not in any other way afford protection to the purchaser or restrict the operations of the vendor, though incidentally it would enable a retail chemist to offer the same drug or mixture, made up by himself, at a lower price. But to a large majority of purchasers a statement of composition or contents on the label would afford no information whatever. The disclosure that a remedy contains or consists of "acetyl-salicylic acid," or "hexamethylene-tetramine," or "phenolphthalein," or "taka-diastase," or "emplastrum plumbi," or even "acetanilide" or "potassium iodide," would be meaningless to most people; indeed, the simplest substances might acquire distinction from being described in technical chemical language—soap, for instance, a large ingredient of the most popular aperient pills, posing as "sodium oleate and stearate." And if it be rejoined that the popular name should be required to be given, the answer is obvious that many of the most important drugs, such as most of those mentioned above, have no popular name. Further, an accurate statement of contents might be in itself misleading. For example, if "Phosferine" were stated to contain phosphoric acid, almost every purchaser would believe that he was getting assimilable phosphorus. The question also naturally arises whether the purchaser of a penny powder or a 1s. 1½d. bottle should protect himself against injury or fraud, or whether the State should not protect him, as it does against other injuries and frauds. For these reasons exhibition of formula (except in the case of alcohol, poisons, and certain dangerous drugs) does not appear to us to be a proper, practical, or effective measure.

SUGGESTED AMENDMENTS OF EXISTING LAW.

54. It has further been suggested to us, and counsel's opinion in support of the suggestion has been laid before us, that existing laws might be so amended as to afford all necessary protection to the public. For example, the advertisement of goods might, by an amendment of the Merchandise Marks Act, be deemed to be the application of a trade description to such goods. A false advertisement would then become an offence under this Act. Again, in the Sale of Foods and Drugs Act the specific omission of patent and proprietary remedies might be deleted, thus making, under Section 20, the label a warranty, and therefore the wilful use of a false label an offence. These amendments would be of some value, but the question of what is a "warranty" is a difficult one in law, and has been subject to numerous decisions of the Courts. In the worst cases, too, a man might have finished his advertising campaign, "cleaned up" his profits, and left the country before the warranty could be enforced. Further, the suggested amendment of the Sale of

Foods and Drugs Act would be useless without exhibition of formula, and we have already given reasons for regarding that proposal as inadmissible. We are therefore of opinion that amendment of existing laws, involving complicated legislation by reference, would not afford adequate and available protection. If a change in the law is required, it must be new legislation *ad hoc*. We remitted this important question for further examination to Mr. Guy Stephenson, Assistant Director of Public Prosecutions, whose evidence upon this and cognate legal matters has been of the greatest value to us. In the above conclusion we concur with the view he expressed to us after careful reconsideration. The Indecent Advertisements Act, however, urgently requires amendment, and a satisfactory amending Bill was introduced into the House of Lords by Lord Brayne and read a second time on July 12th, 1910.

FINDINGS.

55. After careful consideration of the evidence laid before them your Committee find :—

- (1) That there is a large and increasing sale in this country of patent and proprietary remedies and appliances and of medicated wines.
- (2) That these remedies are of a widely differing character, comprising (a) genuine scientific preparations; (b) unobjectionable remedies for simple ailments; and (c) many secret remedies making grossly exaggerated claims of efficacy; causing injury by leading sick persons to delay in securing medical treatment; containing in disguise large proportions of alcohol; sold for improper purposes; professing to cure diseases incurable by medication; or essentially and deliberately fraudulent.
- (3) That this last-mentioned class (c) of remedies contains none which spring from therapeutical or medical knowledge, but that they are put upon the market by ignorant persons, and in many cases by cunning swindlers who exploit for their own profit the apparently invincible credulity of the public.
- (4) That this constitutes a grave and widespread public evil.
- (5) That in British Dominions and foreign countries severe legal restrictions exist, and that there is a tendency still further to strengthen the law against these articles.
- (6) That no Department of State and no public officer is charged with the duty of controlling the sale and advertisement of proprietary remedies in this country; that the Home Office and the Local Government Board are virtually powerless in this respect; that the Privy Council Office, though supposed to be specially concerned with the sale of drugs, has no initiative in the matter, and in fact, it fulfils no useful function in this connexion.
- (7) That the existing law is chaotic and has proved inoperative, and that successful prosecution for fraud in the advertisement and sale of secret remedies is fraught with the greatest difficulty, though the Public Prosecutor has perhaps not sufficiently tested the powers of the existing law in respect to such cases.
- (8) That consequently the traffic in secret remedies, except as regards scheduled poisons and the grosser forms of impropriety, is practically uncontrolled in this country.
- (9) That this is an intolerable state of things, and that new legislation to deal with it, rather than merely the amendment of existing laws, is urgently needed in the public interest.
- (10) That grave injury is caused to the public by the existing large sale of medicated wines.
- (11) And that while, for reasons already given, it is not desirable to require the exhibition of formula of every secret remedy, nevertheless it is improper that under the protection of the law enormous quantities of alleged remedies should be sold the composition of which is unknown to any person except the manufacturers of them; and that therefore the formulæ of all secret remedies should be required to be commu-

nicated to a competent officer appointed under the authority of a Minister of State, but that such formulæ should not be divulged to any other person except as hereinafter recommended.

RECOMMENDATIONS.

56. Your Committee therefore recommend :—

(1) That the administration of the law governing the advertisement and sale of patent, secret and proprietary medicines and appliances be coördinated and combined under the authority of one Department of State.

(2) That this administration be part of the functions of the Ministry of Public Health when such a Department is created, and that in the meanwhile it be undertaken by the Local Government Board.

(3) That a competent officer be appointed to this Department, with the duty of advising the Minister at the head of the Department concerned regarding the enforcement of the law in respect of these remedies.

(4) and (5) That there be established at the Department concerned a register of manufacturers, proprietors and importers of patent, secret and proprietary remedies, and that every such person be required to apply for a certificate of registration and to furnish (a) the principal address of the responsible manufacturer or representative in this country, and (b) a list of the medicine or medicines proposed to be made or imported.

(6) That an exact and complete statement of the ingredients and the proportions of the same of every patent, secret and proprietary remedy; of the contents other than wine, and the alcoholic strength of every medicated wine, and a full statement of the therapeutic claims, made or to be made, and a specimen of every appliance for the cure of ailments other than recognised surgical appliances, be furnished to this Department, such information not to be disclosed except as hereinafter recommended, the Department to control such statement, at their discretion, by analyses made confidentially by the Government Chemist.

(7) That a special Court or Commission be constituted with power to permit or to prohibit in the public interest, or on the ground of non-compliance with the law, the sale and advertisement of any patent, secret or proprietary remedy, or appliance, and that the Commission appointed for the purpose be a judicial authority such as a Metropolitan Police Magistrate sitting with two assessors, one appointed by the Department, and the other by some such body as the London Chamber of Commerce.

(8) That the President of the Local Government Board (or Minister of Health) have power to institute the necessary proceedings to enforce compliance with the law, the sale and advertisement of any patent, secret or proprietary remedy, or appliance.

(9) That a registration number be assigned to every remedy permitted to be sold, and that every bottle or package of it be required to bear the imprint "R.N. . . ." (with the number), and that no other words referring to the registration be permitted.

(10) That in the case of a remedy the sale of which is prohibited, the proprietor or manufacturer be entitled to appeal to the High Court against the prohibition.

(11) That the Department be empowered to require the name and proportion of any poisonous or potent drug forming an ingredient of any remedy to be exhibited upon the label.

(12) That inspectors be placed at the disposal of the Department to examine advertisements and observe the sale of proprietary remedies and appliances.

(13) That an annual fee be payable in respect of every registration number issued.

57. Your Committee make the following recommendations regarding the amendment of existing laws :—

(1) That the Stamp Acts be consolidated and amended to remove the numerous existing anomalies and unreasonable exceptions. In this connexion,

pure drugs vended entire under a fancy name should no longer be exempt from duty; the distinction between the name of an ailment, and the name of an organ the seat of that ailment, should be abandoned; and the exemption of medicines generating carbonic acid gas should be omitted (*see* Par. 16). Further, any reference in advertising matter to the Government stamp should be prohibited, and no name of a proprietor or firm should be printed upon the stamp.

(2) That the Indecent Advertisements Act be amended on the lines of Lord Bray's Bill.

58. Your Committee further recommend the following legislative enactments :—

(1) That every medicated wine, and every proprietary remedy containing more alcohol than that required for pharmacological purposes, be required to state upon the label the proportion of alcohol contained in it.

(2) That the advertisement and sale (except the sale by a doctor's order) of medicines purporting to cure the following diseases be prohibited :—

Cancer.	Diabetes.	Locomotor ataxy.
Consumption.	Paralysis.	Bright's disease.
Lupus.	Fits.	Rupture (without operation or appliance).
Deafness.	Epilepsy.	

(3) That all advertisements of remedies for diseases arising from sexual intercourse or referring to sexual weakness be prohibited.

(4) That all advertisements likely to suggest that a medicine is an abortifacient be prohibited.

(5) That it be a breach of the law to change the composition of a remedy without informing the Department of the proposed change.

(6) That fancy names for recognised drugs be subject to regulation.

(7) That the period of validity of a name used as a trade mark for a drug be limited, as in the case of patents and copyrights.

(8) That it be a breach of the law to give a false trade description of any remedy, and that the following be a definition of a false trade description :—"A statement, design or device regarding any article or preparation, or the drugs or ingredients or substances contained therein, or the curative or therapeutic effect thereof, which is false or misleading in any particular." And that the onus of proof that he had reasonable ground for belief in the truth of any statement by him regarding a remedy, be placed upon the manufacturer or proprietor of such remedy.

(9) That it be a breach of the law—

(a) To enclose with one remedy printed matter recommending another remedy.

(b) To invite sufferers from any ailment to correspond with the vendor of a remedy.

(c) To make use of the name of a fictitious person in connexion with a remedy. (But it should be within the power of the Department to permit the exemption of an old-established remedy from this provision.)

(d) To make use of fictitious testimonials.

(e) To publish a recommendation of a secret remedy by a medical practitioner unless his or her full name, qualifications and address be given.

(f) To promise to return money paid if a cure is not effected.

The Report concluded by registering the belief of the Committee that departmental and legislative action in accordance with such outlines would not inflict injustice upon any patent or proprietary medicine or appliance; that it would, alike by its operative and its deterrent effect, afford the public efficient and urgently needed protection against injury and fraud; and that no measures of a smaller scope will secure this result.

The Committee expressed appreciation of the ability and tact of Mr. F. C. Bramwell, whose duties as clerk in connexion with a long inquiry were onerous and delicate.

II.

THE PROPRIETARY MEDICINES BILL

The recommendations of the Select Committee of the House of Commons in 1920 took shape in the Proprietary Medicines Bill, the text of which, as amended in Committee of the House of Lords, is reprinted verbatim here. Amendments were to have been moved on the Report stage, which, however, was not reached.

PROPRIETARY MEDICINES BILL (10 & 11 GEO. V.) AS AMENDED IN COMMITTEE
OF THE HOUSE OF LORDS.

Memorandum.

1. The object of this Bill is to give effect to the recommendations of the Select Committee of the House of Commons on Patent Medicines, who reported in August, 1914: see Paper 414 of 1914. It contains no provisions which were not specifically recommended by the Select Committee, and it includes all their more important recommendations so far as they fall within the province of the Ministry of Health.

2. Provision is made for the establishment of a register of proprietary medicines and appliances, and of the owners thereof, and the Bill prohibits the sale of any unregistered proprietary medicine or appliance.

The expression "proprietary medicine" is defined in the Bill to mean a medicine which is held out by advertisement as of use for curative or remedial purposes, and which is either sold under a trade name or manufactured by a secret process.

Severe penalties are attached to the unauthorised disclosure by the registrar or any other person of the formula of any registered medicine.

3. The sale of remedies purporting to cure certain diseases, such as consumption or cancer, is prohibited, and it is made an offence to advertise any article in terms which suggest that it can be used to produce abortion.

4. The Minister of Health is empowered to remove from the register any injurious medicine or appliance, but the owner is given a right of appeal to the High Court.

5. The Bill, in accordance with the recommendations of the Select Committee, prohibits certain practices, chiefly in connexion with advertisements, which the Committee considered undesirable.

6. All regulations made under the Bill are required to be laid before Parliament.

Arrangement of Clauses.

1. Control of manufacture and sale of proprietary medicines and appliances.
 2. Prohibition of sale, &c., of remedies for certain diseases.
 3. Offences in connexion with advertisements.
 4. Register of medicines and appliances.
 5. Regulations.
 6. Removal from register of medicines and appliances.
 7. Appeal against removal from register.
 8. Penalties.
 9. Saving for sales on medical prescriptions and sales of existing stocks.
 10. Interpretation.
 11. Short title and extent.
- Schedule.

TEXT OF THE BILL.

Intituled

An Act to regulate the manufacture and sale of certain medicines and surgical appliances, and for purposes connected therewith.

Be it enacted by the King's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

*I.—Control of Manufacture and Sale of Proprietary
Medicines and Appliances.*

(1) It shall not be lawful for any person to manufacture or prepare for sale any proprietary medicine or any proprietary surgical appliance unless—

(a) he is duly registered under this Act as the owner of the medicine or appliance, as the case may be, or is a person authorised by the registered owner to manufacture or prepare for sale the medicine or appliance on his behalf; and

(b) the medicine or appliance is a medicine or appliance duly registered under this Act; and

(c) in the case of a medicine, it is compounded of the ingredients and in the proportions specified in the register, or, in the case of an appliance, it corresponds with the specimen furnished under this Act to the registrar.

(2) It shall not be lawful for any person to sell, offer for sale, or have in his possession for sale, any proprietary medicine or proprietary surgical appliance which is not registered under this Act, or any proprietary medicine or proprietary surgical appliance registered under this Act unless it bears the number assigned to it in the register, or any proprietary medicine or proprietary surgical appliance which is manufactured elsewhere than in England or Wales unless the owner thereof or his representative is duly registered under this Act.

(3) If any person acts in contravention of this section he shall be guilty of an offence against this Act:

Provided that proceedings shall not be brought against any person for manufacturing or preparing for sale a proprietary medicine compounded of other ingredients or in other proportions than those specified in the register except by the Minister.

(4) This section shall come into operation on the expiration of six months from the date on which notice is given by the Minister in the *London Gazette* that applications for registration under this Act will be received.

II.—Prohibition of Sale, &c., of Remedies for Certain Diseases.

(1) After the expiration of six months from the commencement of this Act it shall not be lawful for any person to sell, or to offer or advertise for sale, any medicine or surgical appliance of any kind whatsoever purporting or stated directly or by implication to be effective for the cure of deafness or rupture or for the prevention, cure, or relief of any of the diseases or infirmities mentioned in the Schedule to this Act.

If the Minister is of opinion that the provisions of this subsection should extend to any other disease or infirmity he may by regulations under this Act add the name of that disease or infirmity to the Schedule to this Act:

Provided that before any regulations are made for the purposes of the foregoing provision, a draft of the regulations shall be laid before both Houses of Parliament, and the regulations shall not be made unless both Houses by resolution approve the draft either without modification or with modifications to which both Houses agree, and upon such approval being given the regulations may be made in the form in which they have been approved.

(2) No person shall print, publish or distribute, or be concerned in any manner in the printing, publication or distribution of, any advertisement or communication relating to any article expressed in such terms as may, or are likely or calculated to, suggest that the article may be used or may operate as a means of producing an abortion or miscarriage.

(3) If any person acts in contravention of this section he shall be guilty of a misdemeanour.

III.—Offences in Connexion with Advertisements.

If any person—

(a) being the registered owner or the vendor of any proprietary medicine or proprietary surgical appliance, or the agent of any such owner or vendor, solicits or invites, whether by advertisement or otherwise, any person suffering, or believing himself to be suffering, from any ailment to enter into correspondence with him, either directly or indirectly, with reference to the ailment, or by correspondence treats or offers to treat any person suffering or believing himself to be suffering from any ailment, or offers to give advice to any person with reference to the cure, relief, or prevention of any ailment or to return money paid therefor if such cure, relief, or prevention does not take place; or

(b) publishes or otherwise makes use of any fictitious, false, or misleading testimonials in relation to any proprietary medicine or proprietary surgical appliance; or

(c) publishes, whether in any advertisement or otherwise, a statement to the effect that a proprietary medicine or proprietary surgical appliance is recommended by a duly qualified medical practitioner without including in the statement correct and full particulars with respect to the name and qualifications and, in the case of a living person, the address of the medical practitioner; or

(d) publishes, whether in any advertisement or otherwise, a false statement to the effect that, or a statement calculated to induce any person to believe contrary to the fact that, a proprietary medicine or proprietary surgical appliance was discovered, invented or compounded by a duly qualified medical practitioner;

he shall be guilty of an offence against this Act.

IV.—Register of Medicines and Appliances.

(1) For the purposes of this Act the Minister shall form and keep, subject to and in accordance with the provisions of this Act, a register of owners of

proprietary medicines and owners of proprietary surgical appliances, and of proprietary medicines and appliances.

(2) The register shall consist of the following parts:—

(a) A register of the persons registered as such owners as aforesaid;

(b) A register of proprietary medicines;

(c) A register of proprietary surgical appliances.

(3) The Minister shall appoint a proper person to be registrar for the purposes of this Act, and shall assign to him such duties in connexion with this Act as he shall think fit.

(4) The register of proprietary medicines shall be kept in two separate books, in one of which (in this Act referred to as "the formulæ book"), there shall be contained the particulars with respect to the ingredients and composition of the medicines, and in the other of which there shall be contained all the other matters which are required to be registered in relation to proprietary medicines.

(5) Notwithstanding anything in Section 14 of the Evidence Act, 1851, or any other Act, the registrar shall not furnish any copy of or extract from any entry in the formulæ book relating to any medicine to any person other than the registered owner of the medicine, and the registrar shall not, except with the consent of the registered owner of a medicine, produce or otherwise disclose the entry in the formulæ book relating to that medicine on any proceedings in any court, other than proceedings against a person for manufacturing or preparing for sale a proprietary medicine alleged to be compounded of ingredients or in proportions other than those specified in the register or proceedings on an appeal against the removal of a medicine from the register.

(6) A certificate purporting to be a certificate under the hand of the registrar stating that any person or any medicine or appliance is, or was at any date, or is not, or was not at any date, duly registered under this Act, or stating that any other particulars are, or were at any date, or are not, or were not at any date, contained in the register with respect to any person, medicine, or appliance registered therein, shall be conclusive evidence in all courts of law of the facts stated in the certificate.

(7) If the registrar or any other person without lawful authority publishes or communicates to any person any information which has, for the purpose of procuring the registration of any medicine under this Act, been furnished by any person with respect to the ingredients or composition of that medicine he shall be guilty of a misdemeanour.

V.—Regulations.

(1) The Minister may make regulations for the following purposes:—

(a) For regulating the formation and maintenance of the register, and providing for the publication of any part of the register other than the formulæ book;

(b) For regulating the manner in which applications for registration under this Act may be made, including the payment of such fees as may be prescribed, and for prescribing the conditions to be complied with by a person applying to be registered as the representative of the owner of any medicine or appliance;

(c) For prescribing the causes for which and the manner in which a registered owner may be removed from the register and the manner in which notice of such removal is to be given;

(d) For enabling particulars entered in the register with respect to any medicine or appliance to be varied or amended, and a new registration number to be issued in any case in which particulars are so varied or amended;

(e) For providing for any matter for which provision may be made by regulations under this Act and for prescribing any matter which is to be prescribed under this Act.

(2) Regulations under this section shall contain provisions—

(a) requiring the prescribed particulars of the name or description under which a proprietary medicine or proprietary surgical appliance is to be sold or offered or advertised for sale to be included in the register:

(b) requiring that in the case of any synthetic drug sold as a proprietary medicine, the chemical name thereof shall appear on the label and in every advertisement relating thereto:

(c) requiring that a number shall be assigned to every medicine or appliance included in the register, and that every vessel or other package in which the medicine or appliance is sold or offered for sale shall bear the registered number:

(d) prohibiting the affixing to or insertion in any such vessel or package as aforesaid of any other reference to the fact that the medicine or appliance is registered under this Act:

(e) requiring every person registered as an owner under this Act, who is not himself the manufacturer of the medicine or appliance, to furnish in the prescribed manner the prescribed particulars with respect to the person by whom the medicine or appliance is manufactured:

(f) prohibiting the registration of any medicine unless and until full particulars of the ingredients of the medicine and the proportions in which those ingredients are used have been furnished to the registrar, including in the case of medicated wines or spirits particulars of the alcoholic strength thereof, and prohibiting the registration of any medicine or appliance until full particulars have been furnished to the registrar of the directions for use which will be supplied with the medicine or appliance when sold:

(g) enabling the Minister, if he so thinks fit, to direct that the name and quantity of any poisonous or dangerous substance forming an ingredient of any registered medicine shall be stated in the prescribed manner on all vessels or other packages in which the medicine is sold or offered for sale:

(h) requiring every proprietary medicine containing more than such an amount of alcohol as is in excess of that required in the opinion of the Minister for solvent or preservative purposes, to bear on the vessel or other package in which it is contained a statement in writing of the proportion of alcohol contained therein:

(i) prohibiting the registration of any surgical appliance unless and until a specimen thereof has been furnished to the registrar:

(j) prohibiting the affixing to or insertion on or in any vessel or package containing any proprietary medicine or proprietary surgical appliance of any statement declaring that the medicine or appliance possesses any therapeutic qualities other than such qualities as are specified in the register as being the therapeutic qualities of that medicine or appliance.

(3) If any person acts in contravention of or fails to comply with the provisions of any regulation made under this section, or furnishes any false or misleading particulars for the purpose of or in connexion with an application made under any such regulation, he shall be guilty of an offence against this Act.

(4) Every regulation made under this Act shall be laid before each House of Parliament forthwith, and if an address is presented to His Majesty within twenty-one days on which that House has sat next after any such regulation is laid before it praying that the regulation may be annulled His Majesty in Council may annul the regulation, and it shall thenceforth be void, but without prejudice to the validity of anything previously done thereunder.

VI.—Removal from Register of Medicines and Appliances.

Subject to the provisions of this section, the Minister may, where it appears to him that any medicine or appliance which has been registered under this Act will or is likely if used in accordance with the directions for use issued therewith, or will or is likely for any other reason, to cause injury to health, direct that the medicine or appliance shall be removed from the register, and where the Minister gives any such direction he shall cause notice of the removal to be given in the *London Gazette*, and in such other manner as he thinks fit:

Provided that the Minister before giving a direction under this section shall send by post to the registered owner of the medicine or appliance notice in writing of his intention in that behalf, and shall take into consideration any representations which may be made to him in writing with respect to the matter by or on behalf of the registered owner at any time within twenty-one days after the date of the sending of the notice, and the Minister shall not give any public intimation of his intention until the expiration of the said twenty-one days.

VII.—Appeal Against Removal from Register.

If any person being the registered owner of any medicine or appliance is aggrieved by the removal of his name or of any medicine or appliance from the register he may within three months after the date on which notice of the removal has been given in accordance with the provisions of this Act, appeal to the High Court against the removal in manner provided by rules of court, and on any such appeal the order of the Court shall be final and conclusive, and shall not be subject to any appeal to any other court.

VIII.—Penalties.

If any person is guilty of any offence which is declared by this Act to be a misdemeanour he shall be liable on conviction therefor to imprisonment for a term not exceeding twelve months, or to a fine not exceeding five hundred pounds, or to both such imprisonment and fine, and if any person is guilty of any other offence against this Act he shall be liable on summary conviction for each offence to a fine not exceeding fifty pounds, and in the case of a continuing offence to a further fine not exceeding five pounds for each day during which the offence continues after conviction.

IX.—Saving for Sales on Medical Prescriptions and Sales of Existing Stocks.

Nothing in this Act shall operate to render unlawful—

(a) the sale of any medicine or appliance to or for the use of any person in accordance with a prescription given in the case of that person by a duly qualified medical or dental practitioner; or

(b) the sale of any medicine or appliance which is proved by the vendor to have been bought by him at any time before the twenty-fourth day of July, nineteen hundred and twenty.

X.—Interpretation.

For the purposes of this Act—

The expression "medicine" includes any drug, preparation or compound of any description whatsoever to be used whether externally or internally for the prevention, cure, or relief of any malady, ailment, infirmity or disorder affecting human beings;

The expression "proprietary medicine" means any medicine which is held out by advertisement, label, or otherwise in writing, as efficacious for the preven-

tion, cure or relief of any malady, ailment, infirmity or disorder affecting human beings and—

(a) which is sold under a trade name or trade mark to the use of which any person has or claims or purports to have an exclusive right; or

(b) of which any person has or claims or purports to have the exclusive right of manufacture or for the making of which any person has or claims or purports to have any secret:

The expression "proprietary surgical appliance" means any instrument or contrivance of a medical or surgical nature which is recommended to the public by advertisement, label, or otherwise in writing, as of use for curative purposes and which is sold under a trade name or a trade mark to the use of which any person has or claims or purports to have an exclusive right or for the making or selling of which any person has or claims or purports to have an exclusive right;

The expression "Minister" means the Minister of Health;

The expression "registered owner" or "person registered as an owner" includes a person registered as the representative of an owner.

XI.—Short Title and Extent.

(1) This Act may be cited as the Proprietary Medicines Act, 1920.

(2) This Act shall not apply to Scotland or Ireland.

PROPRIETARY MEDICINES BILL: SECOND READING IN THE HOUSE OF LORDS.

Viscount ASTOR moved the second reading of the Proprietary Medicines Bill in the House of Lords on July 29th, 1920. He said that this measure was introduced in fulfilment of an undertaking given by the Lord Chancellor on behalf of the Government last year. It had been framed on the recommendations of the Select Committee which reported in 1914. The Committee's recommendations were in the nature of a compromise, and were not based on either of the two conflicting views. This country was very much behind several of our dominions, as well as most other civilised countries, in its treatment of proprietary and patent medicines and surgical appliances. As an example of the way in which our public were victimised the Select Committee quoted the instance of a man who came with a certain instrument to this country and was reported to have made over £60,000 by its sale. He went to France and was sentenced to three years' imprisonment, as well as heavily fined, for trying to sell the same instrument. Additional legislation was certainly necessary here to deal with the matter. At the present moment there was no Minister or Government department which was responsible for protecting the public, or for seeing that the public did not suffer grievous injury. The Bill did not propose to protect the purse of the public, though possibly amendments might be moved later to strengthen the Bill in that respect. Injury might be caused in one or two ways. Sufferers who purchased and attempted to use these appliances and medicines very often postponed going to a proper medical practitioner while trying to treat themselves. The delay very often aggravated their ailment, sometimes very seriously. In other cases actual injury was caused through these remedies. They proposed to prohibit the advertisement and sale of remedies purporting to treat, cure, alleviate, or prevent diseases which were set out in the schedule—cancer, consumption, diabetes, certain diseases peculiar to women, fits, epilepsy, deafness—because they knew that serious risk was involved if sufferers tried to treat themselves by using a patent drug. These were serious complaints, and it was not in the public interest that people, haunted by fear, should be encouraged to use these remedies. Too often they merely touched a symptom of the disease. A case was quoted in the report where a particular medical wine was advertised, and it was stated that if two wine glasses full were taken that was a sufficient amount to cause sleep. It was recommended for children in these words, "For colds, coughs and bronchial affections." It contained cocaine, or the elements of cocaine, and nobody would advocate the continuation of a law which allowed or encouraged people to purchase cocaine in order to make their children sleep when they were suffering from a cough. It was essential that they should take powers to deal with these evils.

In a limited number of cases death was caused, particularly where remedies were used intended to produce abortion. A considerable number of remedies were advertised as being suitable for female irregularities. He was told that at the best these remedies were useless, and that too often the most serious consequences resulted from their use. It was impossible, he was told, to kill an unborn child without endangering the life of the mother. Some of these remedies were intended to give lead poisoning. It was quite true that you might kill the unborn child by this means, but too often they also killed the mother. These remedies also led to blackmail. A case was quoted of two men who had threatened to expose the purchasers of a particular remedy intended to cause abortion. The police intercepted 600 letters containing two guineas each from these unfortunate women, who were paying this money under a threat of exposure. If the Bill did nothing else but prevent this reprehensible practice they would be justified in trying to pass it. The Assistant Director of Public Prosecutions said it was almost impossible to prove fraud, and that practically the law was non-existent. They could not expect the purchaser of a remedy intended to produce miscarriage to come forward after having bought the remedy and say: "I bought this remedy in order that I should be able to commit a crime. I have not been able to produce miscarriage. I have been defrauded." He knew a case where a bottle of mixture was sent with the intimation that the powerful and certain action of the medicine contained in the bottle necessitated the warning that the contents should not be taken by those expecting to be mothers, as the medicine was very liable to cause a miscarriage. That was the way in which these drugs were brought to the notice of a large number of unfortunate women who too often in the past had availed themselves of them. He would quote a brief paragraph from the Report of the Select Committee which summarised, very briefly, the situation. The Committee stated:—

"For all practical purposes British law is powerless to prevent any person from procuring any drug, or making any mixture, whether potent or without any therapeutical activity whatever (so long as it does not contain a scheduled poison), advertising it in any decent terms as a cure for any disease or ailment, recommending it by bogus testimonials and the invented opinions and facsimile signatures of fictitious physicians, and selling it under any name he chooses on the payment of a small stamp duty, for any price he can persuade a credulous public to pay."

The Bill proposed that a register should be made on which every proprietary medicine and surgical appliance and the owners thereof should be registered. The sale of unregistered remedies was prohibited. Powers were taken, subject to the right of appeal, to remove the owner of a proprietary medicine from the register if his remedy was considered too dangerous

to health. Powers were also taken to compel the owner to disclose the contents, the formula, the ingredients to the Government privately and in confidence. Heavy penalties would be imposed for non-disclosure. Further, they prohibited the advertising of remedies purporting to prevent, cure, or relieve the diseases which were set out in the Schedule. Clause 5 stated that the alcoholic contents of a patent medicine must be given on the label. Many of the medicated wines contained as much alcohol as some of the heaviest wines and twice as much as claret. A particular medicine referred to by the Committee which was recommended for use at the time of confinement was found on analysis to contain something like 60 per cent. of alcohol and the rest was apparently pure water. This was recommended as assisting confinement and producing fine and healthy babies. The Bill prohibited correspondence with the vendors, and the enclosure of literature with one remedy recommending the use of another remedy. They also prohibited the advertising of remedies suggesting that they were useful or could be used for procuring abortion. Clause 5 set out that all regulations

must be laid before Parliament. The Minister of Health was made responsible for the supervision of the matters dealt with. In Clause 10 there was a definition of a "proprietary medicine." They excluded from the definition those proprietary medicines which were not advertised, pushed, or puffed in writing as being remedies, or having special therapeutic qualities. They proposed to exclude mixtures the composition of which was known, which were made by well-known and reputable chemists, and which were not pushed for sale on the ground that they had special therapeutic qualities. Nor did the definition include any recognised drug or preparation for which no monopoly was claimed. He knew that the press derived a large revenue from the advertising of patent medicines and surgical appliances, but he had too high an opinion of the press as a whole to believe that they would attempt to stop the passage of the Bill.

The Bill was read a second time, and on Friday, August 6th, 1920, the House of Lords went into Committee on the Bill. Certain amendments were agreed to and the measure as amended was reported to the House.

CONSTIPATION, AUTO-INTOXICATION, DRASTIC PURGATIVES

Petrolagar

(trade mark)

The Solution of the Problem of the Vicious Circle

PETROLAGAR contains 65% of pure medicinal liquid paraffin and 10% of prepared agar-agar in the form of a perfectly homogeneous, stable and highly palatable emulsion. It has effected very remarkable and uniformly successful results in the treatment of the Intestinal Atony which gives rise to Chronic Constipation and Intestinal Stasis. It breaks down the vicious circle—Chronic Constipation—Auto-Intoxication—Drastic Cathartics—and brings about a return to normal in the action of the bowel.

Petrolagar is non-habit-forming, does not leak, and, unlike cathartics, may be administered in progressively decreasing amounts. Microscopic examination of the intestinal content after its use shows intimate admixture throughout the mass—a result unobtainable with plain oil or plain agar-agar. The agar-agar in a table-spoonful of Petrolagar absorbs many times its volume of water and the increased bulk, combined with the lubricating action of the mineral oil, so stimulates peristaltic action that the inertia of the bowel is overcome.

PETROLAGAR is available in four forms:

PETROLAGAR Plain

PETROLAGAR Phenolphthalein

PETROLAGAR Alkaline

PETROLAGAR Unsweetened

Clinical Trial Samples will be sent on request.

Special Supplement
TO
THE LANCET

REX v. BATEMAN

BEFORE THE LORD CHIEF JUSTICE OF ENGLAND, MR. JUSTICE SALTER, AND
MR. JUSTICE FRASER, IN THE HIGH COURT OF JUSTICE, COURT OF
CRIMINAL APPEAL.

On Monday, February 9th, 1925.

REX v. BATEMAN

In the Court of Criminal Appeal Dr. Percy Bateman was granted leave to appeal against his conviction for manslaughter at the Central Criminal Court on Dec. 9th, 1924, when he was sentenced to six months' imprisonment in the second division.¹

The Court was composed of the Lord Chief Justice (Lord Hewart), Mr. Justice Salter, and Mr. Justice Fraser, and the appeal was made on Monday last on Dr. Bateman's behalf by Mr. Norman Birkett, K.C., with whom was Mr. Arthur Davis. Mr. H. D. Roome appeared for the Crown.

OPENING SPEECH FOR THE APPELLANT.

Monday, February 9th.

Mr. BIRKETT. May it please your Lordships. In this case I appear with my learned friend Mr. Davis for the Appellant, and my friend Mr. Roome appears for the Crown. Your Lordships may recall that last Monday your Lordships granted leave to appeal in this case, and this is the appeal by Percy Bateman, who is a doctor. He appeals against a conviction at the Central Criminal Court for manslaughter, a conviction on Dec. 11th, 1924, at the trial before Mr. Justice Shearman, when the Appellant was sentenced to six months imprisonment in the Second Division. My Lords, the grounds of appeal here are: (1) Misdirection as to the law; (2) misdirection as to the evidence; (3) the wrongful admission of evidence; and (4) that the verdict is against the weight of evidence.

SUMMARY OF EVENTS FROM DELIVERY OF THE PATIENT TO HER DEATH.

I made an application last week that although your Lordships were familiar with the facts of the case I might be allowed quite shortly to summarise them in order to assist the later arguments. I desire to do that quite shortly again to-day. The facts were these, that Mary Ann Harding, the deceased woman, was the wife of John Harding who was a builder's labourer at Deptford. The home consisted of two rooms, one a sitting-room-bedroom or a kitchen-bedroom, and the other a bedroom. Those two bedrooms were situate at the top of four flights of stairs, and on the evening when the doctor first attended the room was dimly lighted by a broken incandescent mantle on the gas. Mrs. Harding was 33 years of age. She had had four children, ages 13 to 4. All those confinements had been quite normal. She had been attended in each case by a midwife and she was up to this time a normally healthy strong woman. She was pregnant again in the month of July, 1924, and on July 21st, a Monday, she had slight pains, there was some contest at the trial as to whether they were genuine labour pains or not, at any rate slight pains which passed away. On the 22nd, the Tuesday, there were slight pains again which passed away, but on the Wednesday, the 23rd, she had certainly definite labour pains. About 4 o'clock in the afternoon the pains became so pronounced and so acute that the midwife was sent for, and a Nurse Cleak, who had had 37 years' experience as a midwife, came in the

afternoon. She made her usual preparations as to dressing the patient, and so on, and then made a short manual examination of Mrs. Harding, and the midwife then discovered that there was an obstruction with which she was not competent or willing to deal. That was at about 6 o'clock in the evening and thereupon the doctor was sent for and at about 10 o'clock that night Dr. Bateman arrived at this house. He was informed by Nurse Cleak of one or two material matters, the previous labour pains and matters of that kind, and he then proceeded to make his examination. First of all he had a manual examination by means of the finger. Then, discovering the obstruction which had troubled the midwife, he administered chloroform and thereupon used the forceps for quite a short time, and then, finding that the forceps slipped, he abandoned the use of the forceps and for an hour afterwards was engaged in the attempt to remove the obstruction by the process which I understand to be known as version—merely turning the child. It was, according to the doctor, the most difficult presentation that is known to medical science: the head, feet and the cord all presenting together. The evidence was that for an hour he worked strenuously until the sweat came from him and at the end of the hour the child was delivered dead. The child was placed upon the bed and then the doctor turned to remove the placenta or after-birth. It was referred to by the learned Judge in his summing-up as membranous stuff, which may have rather confused the Jury, because, as I understand, the placenta itself (and it is important to remember this in connexion with the facts of this case) is a thick fleshy cakelike substance which is a span in breadth, an inch in thickness and a pound in weight, which certainly is not very accurately described as "membranous stuff." He turned to remove the placenta, and did so, and a chamber was held by the midwife, Nurse Cleak, to hold the placenta, and it was placed therein; and he was turning to go, having done all that he could, when the nurse called his attention to the placenta in the chamber, and the conversation, which I think is important, was shortly this. The nurse said: "What is this? I never saw anything like that before." The Appellant said: "Good God! What have I done." The nurse said: "I do not know what it is." The Appellant said: "Don't you know what it is?" The nurse said: "No, I don't, I have never seen anything like it before"; and the Appellant said: "It's the uterus." The nurse said: "Surely not." The Appellant said: "Whatever shall I do?" The nurse said: "I don't know"; and the Appellant said: "I will tell you." He then

¹ THE LANCET, Dec. 27th, 1924; Jan. 3rd, 1925; Feb. 7th, 1925.

removed the uterus from the placenta and wrapped it in a napkin and placed it in his bag and he took it away and he said to the nurse that she must not say anything so as not to shock the relatives; and later he said: "We had better keep this to ourselves and not shock the relatives." The nurse asked him if the patient ought not to go away to the hospital and he said that he would see in the morning. He then left the room and saw the husband and a friend, a Miss Lehoux, and he told the husband that the child had been born dead, that the wife was very bad and that she probably would not live, that she was about to die, and he told the same to Miss Lehoux, and the husband said: "Ought she not to go away?" and the Appellant said: "Not at present, she must not be moved to-night"; and the husband went with the doctor to the surgery for medicine about 1 o'clock the following morning. Now may I stop there in that short narrative. In this case it appeared, so far as one can judge, that two allegations were made against the Appellant. In point of time the first allegation stopped there—namely, the conduct of the operation of version and producing the child. That is No. 1. The second allegation, as I understand it, was confined to events which followed thereon. Just before I very shortly summarise the second matter, may I say this. It would appear from the post-mortem examination upon July 30th, the woman having died upon the 30th, that the injuries from which the woman suffered at that time might be described, as they were described by the medical witnesses for the Prosecution, as the destruction of the pelvic floor. The uterus, with one of the Fallopian tubes, the right Fallopian tube, and the right ovary had been removed with the placenta. There was a slight tear of 2 in. in the uppermost part of the bladder; there was a crushing of certain intestines against the sacral promontory, which I understand to be a part of the bony pelvic circle which encloses the pelvic cavity, and there was a slight tear in the rectum. That was the extent of the injury. It was alleged at the trial that some of those injuries may have been caused by natural labour—that was urged for the Defence. There is no question that at the post mortem those injuries were existent.

MR. JUSTICE SALTER. The doctors who were called for the Defence were inclined to think, were they not, that those injuries were caused in the course of the version?

MR. BIRKETT. Yes, they were.

MR. JUSTICE SALTER. They said that in their view it was possible that they might have been caused by natural labour, but probably by the manipulation.

MR. BIRKETT. Yes, that is exactly accurate. One of the doctors said that in his personal practice he had known a case where there had been injury by natural labour, but he did say, and it was quite clear their view was, that it had been caused in the manual traction later. Now shortly on the second head, the facts were these, and it is rather important, I think, that I should put the full strength against me in face of the subsequent argument. He said: On Thursday, July 24th, at 9 o'clock in the morning he saw her, the child being delivered somewhere about midnight, and he had gone at 1 o'clock, or early the next morning, she was weak, conscious, could speak, but was vomiting a little. He called again at night and more medicine was obtained for her. The next day, Friday, 25th, he made two visits again. It is said by the relatives she seemed a little better herself, weak and vomiting. The importance of what the relatives said I think lies in this, that it was contended for the Crown that that being so she might have been removed earlier for an operation; I think that is the whole weight they attach to what the relatives said. On that day Nurse Cleak went up to the doctor's, and the purport of what she said (I need not read the conversation) is:

"Do not you think it is advisable to send this poor woman to the hospital?" and the doctor said, "Not at present; we must see how she goes along." On the Saturday he made two visits again. The situation was practically the same. On Sunday, July 27th, he made two visits again, and on that day the nurse went again to the surgery and substantially the same kind of conversation took place, namely: "Don't you think this poor woman ought to go to the hospital?" and the answer given I think I ought to read. "Oh, Doctor, you ought to send her away, poor dear, she is so bad; she cannot get the treatment at home"; and he said he would when she got a bit better; and the nurse said: "She will never get better, she will go under." On Monday, the 28th, the husband asked in the morning if his wife could be taken away to the hospital as she was worse and the strain of looking after her at home during the night was getting intolerable; and the doctor made answer to that that he would send her a sleeping draught to see if she could not get a little rest, and he would go in the evening and see what he could do. The husband went at 6 o'clock again on the Monday and when he got back at 7.30 he found an order for the removal to the hospital. Summarising that matter, it appears from the evidence that there were five requests made to the Appellant, at least matters put before him for his consideration as to the desirability of removing the woman to the hospital, one on the 23rd by the nurse and the husband, one on the 25th by the nurse, one on the 27th by the nurse, and one on the 28th by the husband. Now on Thursday, the 29th, at the hospital she was conscious until 9 or 10 o'clock and she died at 1 o'clock on the 30th. The Coroner's inquest was held on the 30th, and, as I understand it, the post mortem took place that day. Now, my Lords, substantially, and I think accurately, those are the short facts in regard to this matter, and the case for the Prosecution, as I understand it, and as I desire to deal with it, is this.

THE CASE FOR THE PROSECUTION AND FOR THE DEFENCE.

It was said (1) the fact that this injury took place to this woman on the 23rd when you were attempting to deliver the child was in itself evidence of such negligence as, upon the Jury being satisfied that it existed, you could be convicted criminally of manslaughter; (2) either in addition thereto or alternatively (and I want to say something about this when I deal with the summing-up) when that situation had arisen and those injuries which were revealed by the post mortem on the 30th were made known—when that situation had arisen and you knew the uterus had been taken away with the Fallopian tube and the ovary, there was a duty laid upon you to see that you did something to remedy that state of affairs, and because you did not do it you were guilty again of that kind of negligence which renders you liable to a conviction on a criminal charge of manslaughter. Then, of course, it was said that either one or both contributed to, caused, or accelerated, the death of this woman.

The answer in a word that the Defence made—and I will deal with the evidence when I deal with what I submit was misdirection—is: (1) There was not at any time here negligence at all; (2) so far as the first part of the case is concerned, the Prosecution never alleged any act of negligence; (3) that so far as the second allegation of negligence is concerned the conduct of which you complain was considered conduct, as we submit the proper and the prudent conduct, and the Defence pointed to this overwhelming fact which in my submission was never put to the Jury in the form which I respectfully suggest it ought to have been, that of the three known recorded cases where a uterus by misadventure of this kind had been removed, one died within 30 minutes, one died on the way to hospital, and the other died 40 minutes after admission, and in our case by our treatment she had lived seven days, and yet we were

charged with accelerating the death. Now substantially that was the case that was made and the case that was put in opposition, and that being so I desire now to take my first point with regard to misdirection in the summing-up as to the law.

The Force used During the Manipulation.

Mr. BIRKETT. My Lords, the first point that I was desirous of dealing with quite shortly was the submission on behalf of the Appellant that there was here a misdirection as to the law applicable to the facts of this case.

Mr. JUSTICE SALTER. Before you go to the summing-up, will you tell me this. Was it alleged by the Prosecution or admitted by the Defence that there was negligence in the manipulation, assuming that that caused the ruptures?

Mr. BIRKETT. The answer to that is that it was certainly not admitted by the Defence. It is a matter of some conjecture as to whether it was persisted in by the Prosecution.

Mr. JUSTICE SALTER. I did not mean so much that. I meant as to the actual evidence. Was Sir Bernard Spilsbury or Dr. Donald Buchanan asked to say or to express the opinion that it was negligent to have used manipulation with very great force?

Mr. BIRKETT. The question was not so put. My Lord, I think all that it went to was this, that the questions asked were these: Would it need a very sharp pull or a very sharp tug?

Mr. JUSTICE SALTER. I was not talking about that. I was going to ask you about that afterwards. I am not speaking of the removal of the uterus, but of the other severe manipulation which resulted in delivering the child and probably accelerated the internal ruptures. Was that said to be a thing which a person of ordinary care and skill should not have done?

Mr. BIRKETT. No. On the contrary, Dr. Spilsbury, when questions were put to him by Counsel for the Crown, made answer that it was not an unusual thing.

Mr. JUSTICE SALTER. I do not want to interrupt your argument.

Mr. BIRKETT. I am obliged to your Lordship. That was so. It was put to Dr. Spilsbury by Counsel for the Crown: "What do you say about a man taking an hour; is that an unusual thing to do?" and he said, "No," and it was conceded throughout the case that so far as that operation was concerned, having regard to the difficult presentation, it could not be alleged there was a negligent act anywhere.

Mr. JUSTICE SALTER. Now coming to the next point, I want to ask the same question in regard to the removal of the uterus with the afterbirth. Was it suggested that in the circumstances of the case that was a thing which a person of average skill and care would not have done?

Mr. BIRKETT. No. The position with regard to that I think was this, that Dr. Spilsbury and Dr. Buchanan were both asked what amount of force would be needed to pull away or tug away the uterus, or tug away the placenta, and they said it would not require very much force, leaving the inference for the Jury that the man having said that he did use some force, the force so exercised was negligence. I think that is the way it was put. Just this further word. Sir Edward Marshall Hall, who led at the trial, in his observations to the learned Judge as to the law after the close of the case for the Prosecution makes the statement which appears upon the Notes: "It has never been alleged that there was any negligence in the operation," and then the learned Judge said: "Well, I think there is some evidence of it, and unless Mr. Percival Clarke desires to relieve you of any part of the case I propose to leave it to the Jury."

Mr. JUSTICE SALTER. Yes.

SUBMISSION AS TO MISDIRECTION IN THE SUMMING-UP.

Mr. BIRKETT. Now, my Lords, I was about to say that perhaps the most convenient way of putting my points precisely would be to read the part of the summing-up which purports to deal with the law. That I think appears at pages 138, 139, and 140 of the transcript. There are, of course, references throughout the summing-up which I have tabulated on the pages, but the substantial part of the direction as to the law is on those three pages. The learned Judge says: "Members of the Jury, this is a tragic case. It has been argued, and you have heard the evidence of very eminent people, and I am glad you heard it because it is a matter which demands your most anxious consideration, and I am sure will receive it. The charge against this man, who is a member of the medical profession, is that he by gross negligence has caused the death, or, if he has not caused it, has accelerated the death of a woman. It is a serious charge and I think you quite understand it. Although we are dealing with matters that laymen find it difficult to understand I think some of you have been in the jury-box before and understand this, that the function of the Judge is to explain the law to you, and also, to the best of his ability, marshal the facts and put them in detail to you, but the sole question as to what inferences are to be drawn from the facts which you find to be true, and how far you believe or trust one witness rather than another, is entirely for you. I will endeavour to do my part of the matter, and I am sure you will do yours. I want first of all to explain the law to you. The law is that anybody who causes the death of anybody else—it does not only apply to a doctor, it applies to motor drivers, railwaymen, or signalmen—it applies to a number of people—anybody causing the death of anybody else is criminally responsible. It is equally clear law that no one is criminally responsible for what I call making a mere mistake, and it is really for the Jury to draw the line between what is called making a mere mistake, an error of judgment, and doing something that is grossly and palpably wrong. I have only one objection to make to the law as put before you by the Counsel for the defence: That a man is bound to do to the best of such skill as he has." I ought to interpolate here to say that I think the transcript must be a little unjust to the learned Judge in several matters to which I shall make reference. "That a man is bound to do to the best of such skill as he has"—there is something not accurate there. "A medical man who practises for profit the medical profession professes skill; he does not come and say: I am an unskilled person—he is engaged and professes skill. Of course, you will understand it is not for every humble man of the profession to have all that great skill of the great man in Harley-street, but, on the other hand, they are not allowed to practise medicine in this country unless they have acquired a certain amount of skill; they are bound to show a reasonable amount of skill according to the circumstances of the case, and you have to judge them on the basis that they are skilled men, but not necessarily so skilled as more skilful men in the profession, and you can only convict them criminally if in your judgment they fall below the standard of skill which is the least qualification which any doctor should have. You should only convict a doctor of causing a death by negligence if you think he did something which no reasonably skilled doctor should have done. It was said a long while ago by a great Judge where a surgeon was convicted—it does not follow because he was convicted this one should be—'You as a Jury are concerned,' [here Mr. Birkett quoted the Judge's words to the Jury, defining what was meant by "degree of skill."]

Mr. JUSTICE SALTER. Have you discovered the case to which he made reference?

Mr. BIRKETT. No. I have made, if I may say so, the most exhaustive inquiries, and my learned friend Mr. Roome, who was present at the trial, has not been able to assist save to suggest that it was possibly Williamson's case; but it could not be that case because there was no conviction in that case and the prisoner

was not a surgeon. I think I have the case to which he made reference, and I will read it in one moment. "You have got to consider if this man in anything he did fell below the level which you expect of a doctor—below that degree of skill which you have the right to expect of a doctor—by no means the extreme skill which everybody knows of, but that degree of skill which you expect from a doctor who attends an accouchement and who is taken to know his business. There is one other thing about the law I have to say, and that is, some doctors at times have to deal with people who are very ill and are bound to die, and it is no good to say, 'Oh, I gave the wrong physic, but she would have died afterwards'; and I shall leave it to the Jury to say whether the death was caused or accelerated by the treatment administered. In adopting the word 'accelerated' you have got to act with great caution. It really means this: That you think by the treatment the patient died when otherwise she would not have died substantially at the time she did. You will consider carefully, and it is only right that you should consider carefully: Well, if he had done something else she would have lived a day longer, and whatever her chance was her chance of living was taken away by his attitude. You will apply that test. That is all the law I will explain to you." In addition to that, without troubling your Lordships with regard to the pages, at various stages when the learned Judge was dealing with the facts he used phrases to which I shall make reference if need be. He used the phrase "gross negligence" frequently. He used "gross and culpable negligence." He used "gross dereliction of duty," "gross wicked neglect and culpable neglect of duty," and "breach of duty." They were phrases which he used when marshalling the facts. But the law, I think, is comprehended in the passages which I have read.

The Distinction between Civil and Criminal Negligence.

Now my first observation with regard to the matter is as follows: It is to be noticed that there is here not one word which makes any distinction between what may be called civil negligence and criminal negligence, and in my submission that is a factor in this case of the very supremest importance, that while the summing-up might be quite unexceptional from that point of view of an action for damages against a doctor—and indeed a good many of the phrases which I have read would seem to point to that end—that in so far as it is a direction to a Jury on a criminal charge that omission in the summing-up is fundamental and is fatal to this conviction. Of course, I am perfectly conscious of the very great technical difficulties arising on the distinction one makes between civil negligence and criminal negligence. Both things, as I appreciate it, are proved by the same facts and Juries draw the inference from the facts, but unless a clear distinction is made and the ground for it made, then in my submission a grave injustice could be done to any prisoner, and certainly to any medical man, the technical distinction, as I understand it, being that civil negligence is that negligence in which reparation is sought by an individual, criminal negligence is that negligence in which reparation is sought by the State, one being private and the other being public. That being so, the State would not interfere with a matter of this kind unless there was something substantial and something which in its essence differs from that which may be termed civil negligence. My Lords, it is to be noticed right at the very outset that in all that discussion with the Jury as to the elements which constituted this crime, there is that first omission, that not one word is said to them that you must distinguish in this case between the ordinary case where there might be an action for damages, where the degree of skill would enter into it, and this case, where the charge is manslaughter.

Mr. JUSTICE SALTER. No doubt there may be that distinction often drawn in charging Juries in cases of manslaughter, and I suppose it is generally

in the interests of the accused that it should be drawn; but are you sure that it is in any way necessary to do it, or even that it is desirable to do it? What have the Jury to do to establish the negligence which is set up in different circumstances? Is it not rather a complicated way of going to work, first of all to explain to them a safe standard and then say there must be some addition to that?

Mr. BIRKETT. In my submission it is both necessary and certainly, with greater force, it is desirable. I ventured in my prefatory words to say that I did appreciate how difficult this matter is to put to a lay Jury having regard to the distinction which ought to be drawn between civil and criminal negligence, and how frail the margin between the two may very well be; but in its absence, and particularly in a case like this—your Lordship uses the word "desirable"—can it be doubted that the sympathy of every single man on the Jury was with the husband and with the poor dead woman? The ordinary instinct of mankind, when you hear a narrative of the suffering and the pain and the misery that poor woman endured, is to say it might very well have been avoided, and if it were, it might be a case where civil remedies applied. It is a very difficult thing as to the ingredients of the matter when it becomes a criminal offence. Now may I put, not in detail, the two points arising out of that main position. I submit it is a misdirection to say to the Jury on a criminal charge: "You can only convict them criminally if in your judgment they fall below the standard of skill which is the least qualification which any doctor should have." In my submission, it has no application to a crime at all. I submit with very great respect and deference it is an admirable matter when dealing with a civil action, but to say of a doctor who is in the dock charged with manslaughter you can only convict him criminally if in your judgment he falls below the standard of skill which is the least qualification a doctor should have—

The LORD CHIEF JUSTICE. The expression, no doubt, is concise. Is not the learned Judge there meaning, going back to the phrase in which he summarised the contention of the Defence, that there are two elements; first of all there is the implied undertaking of reasonable and competent skill; secondly, there is the obligation to exhibit that skill in fact. Those observations to which you are now referring are observations under the first head. You must not say that a doctor who holds himself out to do a doctor's work is negligent because his skill falls short of the highest skill. You can only say that he is negligent in that first sense if his skill is not such as is reasonably to be expected of a practitioner.

Mr. BIRKETT. My Lord, I so apprehended it, and my submission is that on that apprehension it is a misdirection; that in a criminal charge the question is not whether this man fell below the standard of skill, but the question is, was he negligent? and your Lordships are probably familiar with this: there is a passage in *Beven on Negligence* which I think puts this matter clearly.

The LORD CHIEF JUSTICE. Do you say that the *spontis expertum artis* has no relation to negligence as a crime?

Mr. BIRKETT. No. What I say with regard to the position is this, that so far as the negligence in crime is concerned, what the Jury have to find, upon a proper direction (as I say, the margin is small) is that the negligence was something different from the negligence which would be a matter of civil liability, and something which is so gravely wicked and wrong that it is out altogether of the category of civil negligence and comes within the definition of crime.

Mr. JUSTICE SALTER. I am not sure that you answered my Lord's question. I will put it in my own way. Take a case where there is a very gross lack of skill, and no lack of care at all. Suppose an unqualified person performs an operation and is grossly

ignorant and kills a patient, but it is admitted that he did his utmost and used every faculty to the extent of his small skill. Could he not be convicted of manslaughter?

Mr. BIRKETT. It would depend on the facts. If in fact the patient, knowing that, had gone to him, then he could not be convicted. Your Lordship probably remembers the case where a man went to a farrier for some surgical operation, and the answer was: If you had not been an ass this would never have occurred. You would not have gone to a farrier. It was held it was no felony; and in any event (I propose to cite a case on this point) that when you are dealing with the crime of negligence, in my submission to speak of the degree of skill is quite irrelevant, and that the real point is, were you negligent with such skill as you had.

The Standard of Skill.

The LORD CHIEF JUSTICE. Then you are really setting up the standard attributed in this passage to the learned Counsel who appeared at the Central Criminal Court; that is to say, you are saying that even when a man holds himself out as a qualified person to perform a difficult and complicated operation, he is not to be judged, as regards skill, by any objective test; he is to be judged by such skill as in that particular case he happens to have?

Mr. BIRKETT. Yes.

The LORD CHIEF JUSTICE. Do you say that really?

Mr. BIRKETT. No, I put it in this way. I do not desire to advance a point which I should shortly have to give up. I say at once that I perceive many intellectual difficulties about this matter; but the degree of care, which is the standard by which the Jury must judge both civil and criminal, of course is dependent in some degree upon the person with whom you are dealing, and if you are dealing with a Harley-street specialist or if you are dealing with a general practitioner, then different standards would obviously apply. But when you have a general practitioner, let us say, who is a qualified man, who does an operation to the best of his skill and knowledge, without any negligence that can be attributed to him, it is no ground for anybody to come along and say: But you are not quite as skilful as the ordinary general practitioner; and it is no element, in my submission, of the crime of manslaughter by negligence to say that you fall below the standard of the general practitioner.

The LORD CHIEF JUSTICE. Now you introduce the words "not quite as." Do you or do you not assert, as a principle of law, that under the head of "skill" the practitioner in such a case is to be judged, not by reference to any general standard of skill, but by reference only to such skill as he in the particular case had?

Mr. BIRKETT. My Lord, I submit the latter. May I cite, in order to fortify myself about that matter, from Beven on Negligence. My volume is the third edition, Vol. II., at page 1156: "The principle of most extensive scope, prevailing throughout all classes of skilled labour, and not confined to medical practitioners, is that he who undertakes the public practice of any profession undertakes that he has the ordinary skill and knowledge necessary to perform his duty towards those resorting to him in that character. Where malpractice is found to have been used, whether the practitioner is qualified or unqualified, ignorant or negligent, matters nothing. The legal wrong is the incompetent or negligent treatment, not treatment by one wanting a qualification; and thus it is that a defence that the patient's treatment has been followed by improvement 'as good as is usually obtained in like cases' is ineffectual where there has been negligence; for the patient is entitled to the chance of the better results that might have followed proper treatment. From the same principle flows the consequence that whether the service is remunerated or gratuitous, is immaterial.

Still the standard of care and competency is perpetually variable. Negligence in one man may be competent care in another. For instance, a specialist consulted in his speciality would be liable for negligence in respect of treatment which in a junior and ordinary member of the profession would more than pass muster; and that might be negligence in a doctor of repute in the west of London which would yet come up to the highest warrantable expectations of the patient of the village doctor in remotest Kerry or Sutherlandshire. Where the charge is of negligent treatment it is obvious that the question of competency or incompetency is irrelevant." My Lord, that is the passage which deals with the various theories of school and practice.

The LORD CHIEF JUSTICE. But does that mean quite what you suggest it means?

Mr. BIRKETT. My Lord, I confess that I have spent a very long time thinking about that passage.

The LORD CHIEF JUSTICE. You see how it begins. It is dealing with the topic of malpractice, and then it goes on to the standard of care and competency, and is not it saying this, that under the heading of "negligence in act" a man is not to be excused because of lack of skill?

Mr. BIRKETT. Yes, my Lord. I think it does say that; that where you are dealing with an allegation of negligence it matters not whether your man is skilled or unskilled.

The LORD CHIEF JUSTICE. But on the other hand, where the negligence alleged is that the man is unskilful, he does not excuse himself by saying he was negligent. It does not work the other way round, in other words.

Mr. BIRKETT. My Lord, even putting it, for the purpose of argument, upon that footing, even then in my submission to say in a criminal charge that you cannot convict him criminally unless he falls below the standard of skill which is the least qualification which any doctor should have, must in my submission be a misdirection upon the law with regard to negligence as constituting a crime.

The Two Elements: Competent Skill and Diligence in Act.

The LORD CHIEF JUSTICE. Is not the learned Judge really saying this, though not quite in so many words: There are two elements: (1) competent skill, (2) diligence in act?

Mr. BIRKETT. Yes.

The LORD CHIEF JUSTICE. As to competent skill, do not try this Defendant by the higher standard of Harley-street; on the other hand, do not try him, as it has been suggested you should, by what you conceive to be the particular degree of skill which he may have. Ask yourselves what a reasonably qualified medical practitioner is to be expected to have in the way of skill?

Mr. BIRKETT. It is. That is the submission that I make upon the first point, and I do not think I can usefully add to it, my submission being first that the summing-up had been vitiated from the beginning by no clear line of demarcation being drawn between civil negligence and criminal negligence, this matter, which might quite properly have been put to the Jury as a matter of testing civil liability, was out of place altogether when you were dealing with crime. My Lord, on the next page there is another matter which I ought to call attention to.

Mr. JUSTICE FRASER. I do not want to interrupt you, but you are going, apparently, to leave this passage in Beven.

Mr. BIRKETT. Yes, my Lord.

MR. JUSTICE FRASER. Will you look at the top of page 1157. You quoted a passage from page 1156.

MR. BIRKETT. Yes, my Lord.

MR. JUSTICE FRASER. You see those first few lines at the top of page 1157.

MR. BIRKETT. Evidence of negligence?

MR. JUSTICE FRASER. The next three or four lines; will you read those?

MR. BIRKETT. Yes, my Lord. "Evidence of negligence is not suggested by an arbitrary standard. Given the presumptive competency of the practitioner, the standard of professional skill he is required to reach is that of the ordinary and average practitioner in the branch, or of the school, to which he professes himself to belong; for a person professing to follow one system cannot be expected to practise any other. Where the amount of skill displayed in treatment is in dispute, the evidence of an experienced practitioner of the school professed by the person charged is admissible to show that the treatment was careful and skilful according to the standard of practitioners professing the tenets of the school." My Lord, my submission, of course, upon that matter is that that would be perfectly applicable and properly applicable where the issue is one of civil liability, but is not applicable where the question is one of crime.

MR. JUSTICE SALTER. I am not quite sure that I understand what you are saying, and of course it is a very important thing. I want you to distinguish in your mind between incompetence and negligence—negligence in the narrower sense.

MR. BIRKETT. Yes, my Lord.

MR. JUSTICE SALTER. You agree, do not you, that in civil matters a man who does his very best may be civilly liable because he is incompetent?

MR. BIRKETT. Yes.

MR. JUSTICE SALTER. But in a criminal matter do you say that a man who has admittedly done his utmost cannot be convicted of manslaughter?

MR. BIRKETT. I do, without hesitation, and I say it upon the submission that in the one case the remedy is against the individual, there is a remedy there provided; but so far as the other is concerned it is an injury to the State, and there is no injury to the State if a man has done the best he can, although he may be somewhat under the skill of his fellow-practitioners.

THE LORD CHIEF JUSTICE. But is not there an injury if, being a skilled person, he undertakes to perform a delicate operation requiring skill, and death follows? I am not speaking of this case, but am putting a hypothetical case. Why is not that a matter in which the State has an interest?

MR. BIRKETT. May I take the case of a quack to make the thing clear? There are many cases in the books, to which I will make reference if need be, where a quack holds himself out as being able to do certain things and to provide proper treatment, and knowing that he does not possess the skill he deceives people by so doing. There, clearly, there would be a case where it would be to the interest of the State to say that this is a crime. But where it is a question that you have a fully qualified medical man doing that which by law he is authorised and entitled to do, the mere question that he may in some degree fall below the general level of the skill of the general practitioner in my submission has no relevance to the crime, though it has, I respectfully agree, to the question of civil liability. That is the distinction which I desire to draw, and why I said at the beginning that in my submission to omit to say to the Jury: "Now at all times remember here the clear distinction which has

been drawn by the policy of the law between civil liability and criminal liability," vitiated all that followed.

THE LORD CHIEF JUSTICE. Your first criticism, as I understand, is that here there was a failure to distinguish civil and criminal negligence?

MR. BIRKETT. Yes, my Lord.

THE LORD CHIEF JUSTICE. Is your criticism upon that point exhausted by what you have now said, about this passage relating to skill?

MR. BIRKETT. No, my Lord, there is another passage which I was just coming to, which is at page 140. I will read again: "You have got to consider if this man in anything he did fell below the level which you expect of a doctor—below that degree of skill which you think you have the right to expect of a doctor—by no means the extreme skill which everybody knows of, but that degree of skill," and so on.

THE LORD CHIEF JUSTICE. That is what you have been dealing with so far.

MR. BIRKETT. Yes. The passage I really want is this passage: Line 63: "I shall leave it to the Jury to say whether the death was caused or accelerated by the treatment administered." With great respect, that is not a direction in law to the Jury upon any issue that they really had to try: "by the treatment administered by the doctor." The question was whether he had been negligent, and here at that particular stage it was a question for the Jury whether the death was caused or accelerated by the treatment administered. The treatment, as I say, may have been right, the treatment may have been wrong.

THE LORD CHIEF JUSTICE. But this is with reference to the phrase: "There is one other thing about the law that I have to say."

MR. BIRKETT. Yes.

THE LORD CHIEF JUSTICE. This is cumulative upon the other. Lack of the proper quantum of skill or lack of proper diligence in act would not be sufficient to convict; the Jury must also be satisfied that by reason of that lack in the one case or in the other or both, the death was caused or accelerated. It is not an alternative. It is bringing the negligence which is alleged into relationship with the death which has occurred.

MR. BIRKETT. Yes, my Lord. If I may put it, adopting respectfully what your Lordship says, again myself in this way: If it is said, now members of the Jury, the question you have to consider, and you must not convict this man unless you are satisfied that he falls below the degree of skill which you would expect of a doctor—

THE LORD CHIEF JUSTICE. And even so, you must not find him guilty unless you are satisfied that by reason of that failure or defect (if you find it to be there) this woman's death was brought about or hastened.

MR. BIRKETT. Yes; that is the way I propose to put it: and even if you are satisfied that he fell below that degree of skill which you are entitled to expect of an ordinary doctor, do not convict unless it was because of the treatment that he so gave that this woman died. And, my Lord, if I may put it now in another way, if the direction be: You have got to consider whether this doctor was an ordinary skilled doctor or if he fell below it, and, if so, whether the treatment he gave was given because of his lack of knowledge—if that be the direction, again I submit it is a misdirection; that the real question for the Jury is never put there, and it really is not to be implied there either; that the real question for the Jury was this: Look at this evidence; look at these facts. Is there

here evidence of gross and culpable negligence which entitle you to say this man is guilty of manslaughter?—not the refinements of degrees of skill, not the very highly contested medical questions as to the proper treatment. On that question your Lordships will remember (and I do not want to take up time this afternoon) that I cited one or two cases, upon the application for leave to appeal: Williamson's case and Spiller's case. Perhaps I may just refer to 3, Carrington & Payne again, because it emphasises much better than I can do myself, the point.

The LORD CHIEF JUSTICE. Is that Williamson's case?

Mr. BIRKETT. In 3, Carrington & Payne, at page 629, there is the case of *Rex v. Edwin Martin van Butchell*. At page 632 there is the *Summing Up*. Your Lordships will remember that case; it was of the disease of the rectum. On page 632: "This is an indictment for manslaughter, and I am really afraid to let the case go on lest an idea should be entertained that a man's practice may be questioned whenever an operation fails. In this case there is no evidence of the mode in which this operation was performed; and, even assuming for the moment that it caused the death of the deceased, I am not aware of any law which says that this party can be found guilty of manslaughter. It is my opinion, that it makes no difference whether the party be a regular or an irregular surgeon, indeed, in remote parts of the country, many persons would be left to die if irregular surgeons were not allowed to practise. There is no doubt that there may be cases where both regular and irregular surgeons might be liable to an indictment, as there might be cases where, from the manner of the operation, even malice might be inferred. All that the law books have said has been read to you, but they do not state any decisions, and their silence in that respect goes to show what the uniform opinion of lawyers has been upon this subject. As to what is said by Lord Coke, he merely details an authority, a very old one, without expressing either approbation or disapprobation; however, we find that Lord Hale has laid down what is the law on this subject. That is copied by Mr. Justice Blackstone, and no book in the law goes any further. It may be that a person, not legally qualified to practise as a surgeon, may be liable to penalties, but surely he cannot be liable to an indictment for felony. It is quite clear you may recover damages against a medical man for a want of skill; but, as my Lord Hale says, 'God forbid that any mischance of this kind should make a person guilty of murder or manslaughter.' Such is the opinion of one of the greatest judges that ever adorned the bench of this country, and his proposition amounts to this, that if a person bona fide and honestly exercising his best skill to cure a patient, performs an operation which causes the patient's death, he is not guilty of manslaughter." Now, my Lord, that is authority for the proposition I was putting forward on Williamson's case, which is the next case in the same volume, which I cited last week, which was the nearest case to be found in the books to the facts of this case—where the uterus was in fact removed believing it to be a part of the placenta. Lord Ellenborough said: "There has not been a particle of evidence adduced which goes to convict the prisoner of the crime of murder; but still, it is for you to consider whether the evidence goes so far as to make out a case of manslaughter. To substantiate that charge, the prisoner must have been guilty of criminal misconduct arising either from the grossest ignorance or the most criminal inattention. One or other of these is necessary to make him guilty of that criminal negligence and misconduct which is essential to make out a case of manslaughter."

The LORD CHIEF JUSTICE. There you see the two elements are clearly distinguished: ignorance on the one hand, inattention on the other.

Mr. BIRKETT. Yes, my Lord. "It does not

appear in this case that there was any want of attention on his part; and, from the evidence of the witnesses on his behalf, it appears that he had delivered many women at different times, and from this he must have had some degree of skill. It would seem that, having placed himself in a dangerous situation, he became shocked and confounded. I think that he could not possibly have committed such mistakes in the exercise of his unclouded faculties; and I own that it appears to me, that if you find the prisoner guilty of manslaughter, it will tend to encompass a most important and anxious profession with such dangers as would deter reflecting men from entering into it." There is nothing said there in regard to the standard of skill, or that the man fell below the general standard of skill; it is put clearly, either gross ignorance or criminal negligence, and in my submission, when dealing with the question of crime, that is the proper thing in that event to do.

Mr. JUSTICE SALTER. Mr. Birkett, that judgment of Lord Ellenborough is fatal, is it not, to your contention?—that a man who does his best cannot be convicted for manslaughter? That judgment appears to lay it down that a man who does his utmost may be convicted of manslaughter if he was grossly ignorant.

Mr. BIRKETT. I said that if a man holds himself out to be a skilled man, when in fact he was a quack, it is quite clear he could be convicted of manslaughter for purporting to have that skill, purporting to be a medical man and performing an operation, when in fact he had no such skill or no such schooling.

Mr. JUSTICE SALTER. That is a different thing to manslaughter. You see, in some cases of civil negligence, where there is a holding out as to competence, it is in the nature of a breach of contract.

Mr. BIRKETT. It is.

Mr. JUSTICE SALTER. It is in the nature of a breach of contract. But you cannot say that, for example, in the case of a person who is a beginner at driving a motor car, and who goes out and drives and kills somebody, he taking the utmost care but being quite incapable of driving. Such a person would be liable to be convicted for manslaughter.

Mr. BIRKETT. Yes, I think so.

Mr. JUSTICE SALTER. Although there is no implied contract there.

Mr. BIRKETT. No, but that would be on the ground that he purported to have that skill required of a driver, when in fact he had not. But it would not be a question as to the degree of his proficiency as compared with the general standard of motor drivers; it would be a question whether he was in fact negligent in the circumstances in taking the car out when he knew that he had not the capacity to drive. Let me take a skilled motor driver, who had been driving for many years. The question would not be, did he fall below the general standard of motor drivers, but the question would be: with the skill that he had, was he in fact negligent on this particular occasion; and the degree of skill or the difference in skill between that driver and other drivers in my submission would be quite irrelevant.

The LORD CHIEF JUSTICE. Have you looked at the case of *Rex v. Burdee* (86 Law Journal, K.B., p. 871) which refers to the judgment in the case of *Spiller*. In the case of *Spiller* apparently it was held that gross ignorance is enough, and that doctrine was re-affirmed in the case of *Burdee*. "Any person, whether licensed or unlicensed, who deals with the life or health of any of His Majesty's subjects, is bound to use competent skill, and sufficient attention; and if the patient dies for want of either the person is guilty of manslaughter."

Mr. BIRKETT. I am not contesting that, my Lords.

The LORD CHIEF JUSTICE. I understood you to say—I may be quite wrong—that part of your argument was that questions of skill though relevant in civil matters are not relevant in a criminal inquiry.

Mr. BIRKETT. They are relevant, my Lord, in the jury estimating the standard of care. If you are dealing with a medical man and a layman two different standards are then applicable. If a man who was not a skilled man professed to be a medical man and undertook to cure people that would, in my submission, be in an entirely different category to the case of a medical man who was doing that which he was ordinarily and customarily employed to do. Spiller's case was the case of a corrosive and dangerous plaster, and the child was two years and eight months. This was put to the jury: "The law as I am bound to lay it down (and I believe that I lay it down as it has been agreed upon by the judges, for many cases of this kind have occurred of late more frequently than in former times) is this: If any person, whether he be a regular or licensed medical man or not, professes to deal with the life or health of His Majesty's subjects, he is bound to have competent skill to perform the task that he holds himself out to perform, and he is bound to treat his patients with care, attention, and assiduity." It is not there a question as to the exact degree of skill or whether they fell below the general standard of such persons, whether they have skill or not.

The LORD CHIEF JUSTICE. That case was in the year 1832. Thirty-two years later, in 1864, Mr. Justice Willes in the case of *The Queen v. Markuss* (4, Foster and Finlason) said this: "Every person who dealt with the health of others was dealing with their lives, and every person who so dealt was bound to use reasonable care, and not to be grossly negligent. Of course, negligence might be of two kinds: in one sense where a man, for instance, went hunting and neglected his patient, who died in consequence. Another sort of gross negligence consisted in rashness, where a person was not sufficiently skilled in dealing with dangerous medicines which should be carefully used, with the properties of which he was ignorant, or how to administer a proper dose. A person who with ignorant rashness, and without skill in his profession, used such a dangerous medicine, acted with gross negligence. There again you get the division into two. It may be intention in act or it may be insufficient equipment in skill.

Mr. BIRKETT. The case which your Lordship has just cited, if I may again refer to it, is dealt with in *Beven on Negligence*, Volume 2, page 1158. The learned author in following those cases summarises them in this way: "If a person assumes to act as a physician, however ignorant of medical science, and prescribe with an honest intention of curing the patient, but through ignorance of the quality of the medicine prescribed, or the nature of the disease, or both, the patient die in consequence of the treatment, contrary to the expectation of the person prescribing, he is not guilty of murder or manslaughter. But if the party prescribing have so much knowledge of the fatal tendency of the prescription that it may be reasonably presumed that he administered the medicine from an obstinate wilful rashness, and not with an honest intention and expectation of effecting a cure, he is guilty of manslaughter at least, though he might not have intended any bodily harm."

The LORD CHIEF JUSTICE. What does that purport to be which you are reading?

Mr. BIRKETT. It is the learned author's summary of the decision which your Lordship has just cited.

The LORD CHIEF JUSTICE. With great respect, I think it is better to look at the decision.

Mr. BIRKETT. If your Lordship pleases. I have not the volume here at the moment.

The LORD CHIEF JUSTICE. The next sentence rather helps you, perhaps. "It was not, however, every slip that a man might make that rendered him liable to a criminal investigation. It must be a substantial thing. If a man knew that he was using medicines beyond his knowledge, and was meddling with things above his reach, that was culpable rashness." It must be a question of fact.

Mr. BIRKETT. That is the submission I make with regard to it.

Mr. JUSTICE SALTER. That last case puts it on rather a different footing and puts it in the way which you put it a moment ago when I put the case about driving a motor car. It puts it not that the ignorance itself was a ground for prosecution, but the acting when you are ignorant.

Mr. BIRKETT. I am obliged to your Lordship. That is what I was trying to put to your Lordships a few moments ago with regard to the motor driver. My complaint about the words of the learned Judge in this case is that when you have this passage, which I hope I have not distorted from its context, that "you should only convict a doctor of causing death by negligence if you think he did something which no reasonably skilled doctor should have done," in my earnest submission that is a misdirection in law upon any view of the matter, and whilst it may be said, and I can see that where you have somebody, let us say a quack—

The LORD CHIEF JUSTICE. Is not the rest clearly implied? A man is not being tried for his want of qualifications on paper. He is being tried because he has done something. When the reference is to want of skill what is meant is the doing of this act although he wanted skill.

Mr. BIRKETT. I understood this direction to the Jury to be this. If you think that the removal of the uterus in this case by this man was due to the fact that he fell below the standard of skill which you expect from an ordinary doctor you can convict him of manslaughter. In my submission that is wrong.

The LORD CHIEF JUSTICE. In either case what is involved is the doing of the act.

Mr. BIRKETT. My submission has always had that in mind, when you say to the Jury you can only convict this man if you come to the conclusion that he removed the uterus from this woman which caused her death because he has not the degree of skill you expect in a doctor. In my submission that is a misdirection. The cases discuss the question of skill and the competency where you are dealing with the degrees of skill in any profession and where you are dealing with people who hold themselves out as possessing certain qualifications, whereas they do not hold those qualifications. That is negligence; they do the things recklessly which constitutes the element which makes up the crime. In my submission the omission to distinguish between civil liability and criminal liability and the two passages to which I have referred as a direction to the Jury with regard to the law are such as to entitle me on behalf of the Appellant to say that that was a misdirection in law and, having regard to that fact, I suppose the onus then would be upon the Crown to show that even if there had been any other direction to support that he must necessarily have been convicted.

The LORD CHIEF JUSTICE. You mean so as to bring in the proviso to Section 4: on a right direction the Jury would have come to the same conclusion?

Mr. BIRKETT. The onus would then be upon the Crown to show that upon a right direction they must have come to the same conclusion.

SUBMISSION AS TO WRONGFUL ADMISSION OF EVIDENCE.

I want to pass to the next point, which is in some degree technical, that there was a wrongful admission of evidence. I put it at this stage because in some degree it is rather intimately connected with the summing-up, and if I am right about this, it gravely affected the whole course of the trial. May I put it in this way: your Lordships will recollect the use that was made of the Coroner's depositions at the trial. The Coroner's inquiry was held on July 30th and on that date the Appellant attended and gave evidence. It was upon the evidence which was given at the Coroner's Inquest that Dr. Spilsbury based his view, and it was upon the Coroner's depositions that he gave evidence at all. Those depositions which were so used were never proved and in my submission were quite wrongly admitted, to the great injury and detriment of the Appellant. Would your Lordships look at page 53, Question 697 of the transcript of the shorthand notes in Sir Bernard Spilsbury's evidence. He is asked with regard to his qualifications, and then the next question is: "Did you have an opportunity of reading what the Defendant said at the Coroner's Court?" (A.) Yes, I read the Coroner's Depositions. (Q.) And have you heard the evidence given by Mrs. Cleak, the midwife, and by Dr. Buchanan?—(A.) Yes. (Mr. Justice Shearman): Are you proposing to put those in? (Mr. Percival Clarke): Yes, my Lord. (Mr. Justice Shearman): Perhaps they had better be read now in order that the Jury may know on what Sir Bernard Spilsbury formed his opinion. (Mr. Percival Clarke): Yes, my Lord. If Sir Bernard Spilsbury leaves the box I will prove it. (The witness left the box.) (Mr. Justice Shearman): Gentlemen, this is the evidence at the Coroner's inquiry, and it is what Dr. Spilsbury read; it is Deposition No. 2. If you undertake to put it in afterwards it can be read now. (Mr. Percival Clarke): Yes, my Lord, I will undertake to prove it. (The Clerk of the Court): 'Percy Bateman deposed.' Then it goes on over the whole of the next page. I may have to read it, but I do not want to do so for the moment. On page 55 your Lordships will see at the bottom the reading of the depositions: "I produce a letter I have received from Nurse Dossiter. (Signed) Dr. Percy Bateman."

The LORD CHIEF JUSTICE. That is to say the learned Counsel for the Crown put in a statement made by the Defendant: that statement was a deposition before a Coroner.

Mr. BIRKETT. Yes, my Lord, at that stage it was. Your Lordship sees it says it was signed "Dr. Percy Bateman." In fact it never was signed.

The LORD CHIEF JUSTICE. What is it you are complaining of?

Mr. BIRKETT. A coroner's depositions stand upon entirely the same footing as depositions taken before Justices and must be proved in proper form. These were never so proved, and as they contain some highly controversial statements, on which there was a contest before the Coroner and the Court, in the absence of formal proof—

The LORD CHIEF JUSTICE. How do you say they should be proved?

Mr. BIRKETT. In the same way as a deposition is proved.

The LORD CHIEF JUSTICE. I see that the learned Counsel for the Defendant was not merely present, but from time to time corrected the reading of this deposition.

Mr. BIRKETT. I do not want to press this point further than I ought, but in my submission it is quite clear that the deposition never was proved. If your Lordship looks at the evidence of Waldoock it is quite

clear they were not. I think it is at page 72. He is asked: "Were you present on the 31st July last at the Coroner's Court at Deptford when the inquest was held on the body of Mary Ann Harding?"—(A.) Yes. (Q.) Was Dr. Bateman called into the witness-box?—(A.) Yes." The witness was not in Court. The witness who was called to prove what was said before the Coroner was never in Court at all, and there was no other witness who attempted to deal with the matter at all. The only point of it was, and your Lordships will see it in the summing-up, that there had been a change in the story from the version given before the Coroner and the version given before the Court, whereas it was the same as had been said before the Coroner. The Appellant said: "I went back into the box to contradict him in that matter, and we had a passage of words." It was a point whether the child was in the pelvic cavity or the peritoneal cavity which made a difference.

Mr. JUSTICE SALTER. How did the learned Judge know that the witness Waldoock was not in the Coroner's Court?

Mr. BIRKETT. No, my Lord, he means clearly not in Mr. Justice Shearman's Court; so that he could not say whether what had been read before Mr. Justice Shearman and the Jury was said before the Coroner.

The LORD CHIEF JUSTICE. It is following up Question 885: Did he give the evidence which was read in this Court, and the learned Judge said this witness was not here?

Mr. BIRKETT. Yes, that is the whole of that point, my Lord.

The LORD CHIEF JUSTICE. At any rate, the length to which it has gone is this, that Counsel for the Crown said he had put in the depositions. Then they are read; Counsel for the Defence follows the reading of them. Then a witness is called who swears that Dr. Bateman was called into the witness-box, and that before being sworn he was cautioned; but that particular witness did not happen to hear the re-reading of the evidence that morning.

Mr. BIRKETT. I am, of course, entirely in the hands of the Court with regard to this matter, and I do not desire for one moment to press this point beyond any stage which the Court say I ought not, but I do feel, having regard to the fact that here was a medical practitioner charged upon a matter in which the evidence dealt with medical matters and which were indeed matters of contest which I think cannot be controverted, that the deposition was not proved. With regard to the depositions, whatever the difficulty in the past may have been as to procedure, I submit they are on the same footing as depositions before Justices.

The LORD CHIEF JUSTICE. Do you say that the expert and medical question which was fatal to you was admittedly based on materials not in evidence?

Confusion between the Pelvic Cavity and the Peritoneal Cavity.

Mr. BIRKETT. I would not like to put it so strongly. Sir Bernard Spilsbury based his view, and your Lordships will know what weight the name of Sir Bernard Spilsbury would have with a Jury, on what was said before the Coroner; the important part of that matter was that when the Appellant was before the Coroner he had spoken of the pelvic cavity. Your Lordships will appreciate that on the question of the version and the subsequent manual traction it became important first of all, with regard to the length of time which the operation took, for the Appellant to show how difficult it was. He said the head or some part of it was not in the uterus but in the pelvic cavity. The Coroner thereupon put in brackets "abdomen." A great contest arose then. In order to show negligence of the Appellant it was said he said it was in the abdomen,

the peritoneal cavity. He was either quite mistaken or else he adopted the wrong term, the point being that he denied at all times it was the abdomen or that he ever meant the abdomen or that he ever meant the peritoneal cavity, but what he said was the pelvic cavity, which I understand contains the uterus, the bladder, and the upper organs.

Mr. JUSTICE SALTER. Can you refer us to the place where the Defendant challenged the correctness of this statement?

Mr. BIRKETT. Yes, my Lord. It is on page 120, Question 1365. May I go to page 113 first and then the whole story is complete. "He says that to show what he means by pelvic cavity, so whether you read 'head' or 'child' his explanation is quite impossible, is not it?—(A.) No, it is not; he might quite well use that word 'pelvic cavity.' (Mr. Justice Shearman.) He did not, he says 'the abdomen'—that is the word in the Coroner's deposition—"I do not know whether he said the abdomen or whether the Coroner has written it in, it is in brackets in my copy. Whether that is something the Coroner put in I do not know. It is not signed. (Mr. Justice Shearman.) He signed it, I think. (Sir E. Marshall Hall.) It is not signed; I saw the original yesterday." Then, my Lords, at page 120, Question 1364: "You went and gave your evidence which has been put in?—(A.) Yes. (Q.) You never signed it. Did you ever use the word 'abdomen' with regard to the pelvic cavity, or is it the Coroner's word?—(A.) Pardon me, I think that the Coroner tried to get me to say that the child was in the abdominal cavity, and I rather think that I contradicted him that it was in the pelvic cavity. I think we had a passage of words to that effect. (Q.) Did you ever intend to say that the child was in the abdominal cavity?—(A.) No." Then on page 126, Question 1437 in the cross-examination by my friend there is this: "Did you say before the Coroner three times that the child was outside the uterus and in the pelvic cavity?—(A.) Yes, in the pelvic cavity outside the uterus. (Q.) Out of the uterus in the pelvic cavity?—(A.) Yes. (Q.) Did not you mean by that in the peritoneal cavity?—(A.) No. (Q.) Can you understand how it appeared in your deposition, 'It had been expelled into the pelvic cavity,' and then in brackets 'abdomen'?—(A.) That sentence is incorrect, Sir. I did not say it was in the abdomen. In fact, I went into the witness-box a second time to contradict the Coroner on that point. I think those brackets are made by the Coroner. (Q.) It is plain the Coroner was referring to the peritoneal cavity?—(A.) Yes, and I was not.

The LORD CHIEF JUSTICE. Then the next question is: "You say you and the Coroner were at cross-purposes?—(A.) Yes, I rather think we misunderstood each other. (Q.) By pelvic cavity you mean the vagina?—(A.) Well, what I meant by the pelvic cavity was that part of the body below the brim of the pelvis."

Mr. BIRKETT. In the summing-up, page 153, line 508: "There is only one other matter, and you have to be satisfied before you convict the prisoner, and that is the evidence he gave before the Coroner. It runs as follows, and I will hand it over to you." Then he reads a good deal of it. Then he goes on: "There is no hint of that in his letter; there is no hint until he comes before the Coroner. It is said by the Crown when he is on his defence and he is called to explain, that he is giving a different account to what he gave before. The account he gave then was"—and then the learned Judge goes on to read it. Nothing was said by the learned Judge of the contest which had arisen with regard to what did appear in the particular depositions. The Jury were handed the written deposition without any warning that they must remember in the prisoner's interests what he said about that matter, namely, that the Coroner had not accurately recorded what he in fact said.

The LORD CHIEF JUSTICE. The learned Judge in this passage is not laying stress on the difference between the pelvic cavity and the abdominal cavity.

Mr. BIRKETT. No, my Lord, I do not think he is doing so. That is the whole of the matter with regard to the depositions; as I say, my Lords, I am not anxious to press it one inch further than I should.

Mr. JUSTICE SALTER. Sir Bernard Spilsbury was not re-called to say that this question made any difference.

Mr. BIRKETT. No, my Lord, he was not recalled. In fairness I should say that this is my point; it is nobody else's; it was not taken at the trial. What I mean to say is, the Prosecution were not put on warning at the trial so that they might have re-called Sir Bernard Spilsbury. It does seem to be a point of very considerable substance. You can never tell when you have a lay Jury in highly complicated technical matters how great an effect a matter like that might have upon the Jury. In my submission it cannot be said that that was rightful, and it may very naturally have influenced the Jury in coming to the verdict which they did.

The LORD CHIEF JUSTICE. What was there in fact which might make the Jury more prone to believe the allegation of negligence if he said abdominal cavity than if he said pelvic cavity?

Mr. BIRKETT. As a matter of fact, my Lord, to a layman, or shall I say to me, reading the transcript, the interchangeability by the witnesses of the words "pelvic cavity," "peritoneal cavity," and "abdominal cavity" is very difficult to appreciate.

The LORD CHIEF JUSTICE. You say a Jury of laymen might be more likely to draw an unfavourable inference from "peritoneal" than from "abdominal." I should think it would be more likely to be drawn by a Jury of surgeons.

Mr. BIRKETT. A layman, my Lord, would say the doctor knows what he is talking about; it is not a case of you and me; he knows a pelvic cavity that he is talking about; there is a reason for it. That is the kind of thing which might operate in the minds of a Jury, and the whole of my point with regard to it, in a case in which prejudice might so easily and quickly arise. It is a very unfortunate thing that when there was a grave test about what was said before the Coroner, because it had a very great bearing upon the skill or care that was required for the delivery of a child, that the Jury had that deposition, at any rate with no warning by the learned Judge in the prisoner's interests of how much he admitted and how much he denied.

SUBMISSION AS TO THE PROPER ISSUE FOR THE JURY.

Now, my Lords, I want to come to the third matter. In my submission there was no case to go to the Jury upon the first part of the case, if I may so term it. That is so far as the operation itself is concerned. Without going into any detail at all as to the first part of the case perhaps I may put it in this way: Apart from the evidence of Dr. Buchanan and Dr. Spilsbury, who gave evidence with regard to the probabilities of these matters based upon their medical opinion and knowledge, the testimony was only the testimony of Nurse Cleak as to his conduct at the time of the delivery of the child. I think it is very accurately summarised at Question 332, page 23, where Nurse Cleak says this: "He did everything a doctor ought to do for this woman." She also said "Yes, I thought so." Question 330 is: "Was the only light a broken incandescent mantle?—(A.) Yes. (Q.) Not giving a full light?—(A.) Not much light. (Q.) I will ask you as far as you could

judge, and you have had great experience, did Dr. Bateman seem to do everything that a doctor ought to do for this poor woman?—(A.) Well, I thought so.” That is first-hand knowledge. I think she said she had had an average of 100 confinements a year and had been engaged for 37 years, so that she was manifestly a person of very great experience, and the direct testimony of Nurse Cleak was to that effect. Apart from that it was positively and manifestly in the doctor’s favour. There was nothing in the nature of the evidence of any negligence on the first occasion.

MR. JUSTICE SALTER. You mean on the first occasion, the manipulation and the pulling out of the uterus.

MR. BIRKETT. Yes, my Lord.

MR. JUSTICE SALTER. Of course, they are quite different.

MR. BIRKETT. I mean, my Lord, the conduct of the operation from his arrival at 10 o’clock and the delivery of the child and his going away at 1 o’clock the next morning. I do not think that is suggested. There is certainly no direct testimony about it, so far as I can gather, from the cross-examination of the Appellant. It is said (1) you were negligent, and we ask the Jury to say so because you concealed the removal of the uterus from the relatives and tried to conceal it altogether; it is said in your letter to Dr. Wiggins, which is recorded here—I must confess for my own part that I cannot follow the argument on that,—that you tried to tell Dr. Wiggins by your letter that the uterus was merely introverted, pulled out like a glove and put back, instead of telling him that it was removed. I fail to understand that allegation at all. He said when he took away the placenta the uterus came with it, and it was upon that phrase that it is solemnly suggested that he tried to deceive Dr. Wiggins. Dr. Spilsbury’s opinion was asked about the letter. Then the third matter is that in the depositions before the Coroner there was some variation from the facts. It was said that there was unnecessary violence in pulling the placenta instead of peeling or coaxing the placenta away after the birth of the child. I think those are all the allegations that were made, and now may I shortly deal with them on this submission, that there was really no evidence.

MR. JUSTICE SALTER. Have you not left out the principal point with regard to taking steps to have an operation?

MR. BIRKETT. That, my Lord, I submit, is a separate head altogether. I say quite frankly what my point about the matter is. If I am right, there was no evidence to go to the Jury here. We are in doubt at this moment whether the Jury found their verdict upon the first head, upon the second head, or upon both. That being so, if I can satisfy the Court that there was really no evidence upon the first head to go to the Jury the fact that it was not withdrawn from the Jury at that moment would, in my submission, entitle me to say that this appeal should succeed. If I may take the question of the pulling of the placenta, would your Lordships look at Question 746 on page 59 of the shorthand note. Your Lordships will see that that refers to a matter which Mr. Justice Salter put to me a little while ago. It is in the examination of Sir Bernard Spilsbury: “(Q.) We have heard he was struggling and working hard for an hour. Is that consistent with a proper endeavour to deliver the woman of a child?—(A.) Oh, yes. (Q.) It might take as long as that?—(A.) Oh, yes, and longer. (Q.) The child having been brought into the world what happens next?—(A.) The usual procedure is, after a short time, if the after-birth is not naturally expelled, the doctor assists its expulsion. (Q.) Is the after-birth then retained in the uterus?—(A.) Usually at the time a child is born it is. (Q.) If it is it is part of the duty of the doctor

to take it away?—(A.) Unless it comes away naturally. It practically speaks for itself. (Mr. Justice Shearman.) That is why it gets the name ‘after-birth,’ it usually comes out with the child or shortly afterwards?—(A.) Yes. (Mr. Percival Clarke.) Here we know that when removing the after-birth he removed the uterus too?—(A.) Yes. (Q.) Can you imagine how that came to be done?—(A.) Only by seizing the wall of the uterus and pulling upon that instead of the after-birth, and that would probably only have happened if there were already a tear in the wall of the uterus which would enable it to be seized. (Mr. Justice Shearman.) You are suggesting that putting his hand in to get out the after-birth he caught the tear of the uterus and pulled that instead of the after-birth?—(A.) Yes, my Lord.” That was the view of the obstetricians called for the Defence as well. “(Mr. Percival Clarke.) Would that require force to dislodge it or not?—(A.) Oh, yes, very considerable. (Q.) Have you yourself ever known of a case of a similar kind?—(A.) Yes, I had one case. (Q.) When was that? (A.) About 1912. There was a Coroner’s inquiry in that case also. The doctor by mistake pulled out the uterus and the woman died from hæmorrhage about 40 minutes after it was removed. (Mr. Justice Shearman.) Is that the only case you have ever had in your experience?—(A.) That is the only personal experience I have had of such a case.” Then he goes on to speak of the effect of it, which properly belongs to the second allegation. If your Lordships would look at page 91, Question 1046, Dr. Banister, who was called for the defence, was being cross-examined by my learned friend. He is asked: “Now with regard to removing the placenta. Is that an operation which is usually done very gently by inserting the fingers and, as it were, coaxing or peeling the placenta away from the walls of the uterus?—(A.) Yes. (Q.) Can you understand such force having been used as would tear out the uterus, an ovary, and a Fallopian tube—tear them right out of the woman’s body?—(A.) To tear them right out considerable force obviously must be used. To remove a uterus almost entirely separated as I judge this to have been does not require very much force.” Then my learned friend cross-examined about the broad ligaments. There was nowhere any evidence of anything at any time in that connexion that was done improperly, and no direct suggestion of it at all. So on that matter I submit to your Lordships that there was really no evidence properly to be left to the Jury with regard to the allegation, if that be the allegation relied on. So far as the concealment from the relatives is concerned I should have thought, with very great respect, although it is quite right and proper for the Prosecution to put this matter before the Jury as fully and as strongly as they think they ought, I do not know whether I differ from other people, but the situation is that a doctor has removed the uterus, a terrible thing, in a tenement-dwelling where the poor husband and relatives are waiting in the next room, praying and hoping that all is going well. The doctor knows that she is going to die; he tells the husband she is going to die; he tells the sister and the friend that she is going to die. Was it merely humanity that said: Why distress them and tell them of this dreadful thing that has happened when it can do no good. All that was said on this matter before Mr. Justice Shearman was said by him and said by nobody else. The midwife never said it. He said to the nurse: “Let us keep this to ourselves so as not to shock the relatives.” That is urged as an allegation of negligence in this particular case. In my submission it is not evidence at all.

THE LORD CHIEF JUSTICE. I suppose that it was urged not so much as evidence of negligence as evidence throwing light upon his state of mind about what he had done, thereby intending to exhibit the nature of what he had done.

MR. BIRKETT. The issue, my Lord, for the Jury was not what he had done, but how he had done it; and

the fact that he concealed from the relatives what he had done in my submission is not relevant at all as to how he had done it. I say this, I know my learned friend perfectly well and I do not use the word in any offensive connotation, but it was used prejudicially, having no relevance or pertinence to the point at issue.

MR. JUSTICE SALTER. He took no steps to have an operation when he ought. Does it matter whether the motive was fraud, humanity, or carelessness?

MR. BIRKETT. No, my Lord, I do not think it does matter. In my submission intent would always be irrelevant, and on the question of negligence, strictly argued, those being the two ingredients which form any crime, intent would not matter. I propose to deal as faithfully as I can with the second head, that there was never any evidence to go to the Jury upon the first matter, and the proper course was to have withdrawn it. Would your Lordships just look at the discussion which took place at the end of the case for the Prosecution, because I think it makes quite clear what the real position was. At page 75 Sir Edward Marshall Hall said: "I understand, subject to your Lordship's ruling, that the allegation of negligence here is the omission to have this patient removed to the hospital for the purpose of an operation." That is what I have called the second operation. "(Mr. Justice Shearman.) I think what the Prosecution will have to prove is that either there was grave negligence in any one case in effecting the delivery or in the other in not taking the proper steps after the discovery of the tear to remedy it—either one or the other—and then, the third thing to prove is that the natural consequence of it was the death of the person. Sir E. Marshall Hall.) On the first part I submit there is no evidence to go to the jury at all." There is the submission, my Lord. "The only evidence is that of Dr. Spilsbury, and he was asked: 'In your opinion was the neglect to remove this person to the hospital such as to cause her death?' and he says, 'Yes.' That is the only question asked. It has never been suggested that the actual delivery of the woman was negligent or that the coming away of the uterus was negligent; that has never been suggested. (Mr. Justice Shearman.) I rather thought it was. (Sir E. Marshall Hall.) I submit there is no evidence of it. (Mr. Justice Shearman.) I do not want to say any more than I shall leave it to the Jury. I shall allow Mr. Percival Clarke to conduct his own case, but there is evidence I think for the Jury on both, and the third issue is whether the Prosecution have proved—I do not like to use the word accelerated—that substantially the cause of death at the time it happened was due to the negligence. (Sir E. Marshall Hall.) I will call my experts on that part of the case. (Mr. Justice Shearman.) Unless Mr. Percival Clarke wants to relieve you of any part of the case he will deal with that when your witnesses are called." I submit it is abundantly clear that there was no evidence on the first head to go to the Jury, and I submit the position on behalf of the Appellant is that this having been left to the Jury it is impossible to say whether the Jury convicted on that or convicted on the second, or convicted on them both, and that being so again if that point is good the Appellant here would be entitled to have this conviction quashed.

MR. JUSTICE SALTER. What should have been done if you are right? There is one indictment of negligence and one issue for the Jury. If there is evidence of negligence to go to the Jury it is right to leave the indictment to them.

MR. BIRKETT. But in my submission, my Lord, it was perfectly right to say to the Jury: I have ruled that upon this first head of the case there is no evidence at all, as it is my duty to do, and the only matter, therefore, upon this indictment which you will have to consider will be whether this indictment is sustained by the evidence relating to the second head: Did he take such reasonable steps thereafter as

he should have done, and have left it at large and say there was evidence for them when in my submission there was not? That does entitle this Appellant to come here and make this submission to your Lordship. It raises a very important matter. In a civil action you are entitled to the particulars of negligence alleged, but apparently when you are charged with a much more serious thing and being a medical man, to whom the effect means the loss of every prospect he had in life, the whole thing is at large.

THE LORD CHIEF JUSTICE. Adopting the two-fold division made by the learned Judge at page 275, that is to say, the division into the effecting the delivery on the one hand and remedying what had been done on the other hand, do you say with regard to this evidence that when the learned Judge came to sum up he should have said: There is no evidence of negligence here in and about effecting the delivery. All you have to consider is, was this doctor negligent in the steps he took or omitted to take to remedy the mischief that had been done.

MR. BIRKETT. I say, my Lord, on this first matter that there was no evidence upon this section of the case at all, but having regard to the charges of negligence, the one term that covers most things, the case had been clearly put and clear distinctions made between the first head and the second head; and the submission having been made about that in view of the fact that the defect, if any, in the evidence was not remedied when the Appellant gave his evidence, which would, of course, have cured the matter, the Appellant would have been entitled to say there is no evidence on the first head to go to the Jury.

The Force required for the Removal of the Placenta.

THE LORD CHIEF JUSTICE. Was it not open to the Jury to say upon this evidence that if the doctor had been taking away the placenta it would have been a very simple and easy matter, and that after the evidence had been given as to the considerable amount of force required to tear away the uterus, that he was negligent in tearing it away and that he ought to have known from the amount of force which was required that what he had got was not the placenta. Was it not open to the Jury to say that?

MR. BIRKETT. With great respect, my Lord, I submit that it was not. I have said that I appreciate certain difficulties in this matter of precise definition, if you are entitled to say this thing has happened, you have heard what has been said as to how it happened, the nurse said he did everything which a man reasonably could; nobody else was there to see it happen, that it is open to you to say that because it happened it was negligent.

THE LORD CHIEF JUSTICE. You used the word a few moments ago which learned Counsel for the Prosecution have used about the placenta, "coaxing the placenta." May not a Jury think after hearing the evidence: There seems to be a very great difference between coaxing away the placenta and tugging away the womb?

MR. BIRKETT. Put in that way there is a distinction, my Lord.

THE LORD CHIEF JUSTICE. The point I am upon is your proposition that there was no evidence to go to the Jury about what you might call the first chapter in the case.

MR. BIRKETT. The evidence, my Lord, with regard to the coaxing and peeling was, of course, put in cross-examination by my friend. Your Lordships will, of course, appreciate what the witnesses for the defence said about that. They gave a perfect answer to that matter. I am dealing with the other matter, that there was no evidence to go to the Jury.

MR. JUSTICE SALTER. It was in view of that that I was surprised to find apparently neither Dr. Spilsbury

nor Dr. Buchanan were asked to say anything as to what my Lord has just observed. Something of this kind happened. He said that he got hold of what was the placenta. Ought not he to have known that he had got something more?

Mr. BIRKETT. No, my Lord, the questions were put specifically on the second head about the necessity of the operation, and so on, and not upon the first head. I told your Lordships last week, and I think I am entitled to repeat it to-day, that in the record of the trial it was never really suggested that he had done anything that could be termed negligent with regard to the placenta and the uterus coming away together. Dr. Spilsbury said that the evidence he gave was entirely in accord with the two experts for the defence, namely, that the edge of the uterus having been torn, as indeed was the edge of the placenta, to put your hand in and take one rough edge and mistake it for the other was the most natural thing in the world.

The LORD CHIEF JUSTICE. At that stage, and then you begin to try and withdraw it. The words which you use, I have no doubt quite unintentionally, are always intransitive words, "it came away." The evidence was it was pulled away with considerable force.

Mr. BIRKETT. When Dr. Donald Buchanan gave evidence he was asked in chief at page 46, Question 631: "In order to dislodge it or remove it would much force or little force be required," and he answered: "Well, it is only personal opinion, but I should say a lot of force. I have never known it to be removed. (Mr. Justice Shearman): Is that the first time you have heard of a uterus being removed in the course of delivery?—(A.) In the course of delivery I have never known it occur." Is that really evidence to go to the Jury, my Lords? Mr. Justice Shearman goes on to say: "It is a very remarkable thing to pull out the uterus. I am not saying whether it is wrong or not, but it is a very remarkable thing.—(A.) As a technical point it is beyond my comprehension altogether." So far as evidence is concerned I submit it is no evidence at all which is based upon that.

The LORD CHIEF JUSTICE. There was the evidence upon this point also, was there not, of Sir Bernard Spilsbury at Question 754: "You are suggesting that putting his hand in to get out the after-birth caught the tear of the uterus and pulled that instead of the after-birth?—(A.) Yes, my Lord. (Mr. Percival Clarke): Would that require force to dislodge it or not?—(A.) Oh, yes, very considerable."

Mr. BIRKETT. I am not taking the precise point at the moment, my Lord, but the evidence for the Defence was quite the contrary.

The LORD CHIEF JUSTICE. The point you are on now is that there was no evidence so far as the effecting of the delivery was concerned.

Mr. BIRKETT. I appreciate that that is the point I make, at any rate so far as the first head of negligence is concerned. I think your Lordships are in possession of all the facts relevant thereto. My submission about the whole matter is that there was in fact no evidence to go to the Jury.

THE ALLEGATIONS OF NEGLIGENCE AFTER DELIVERY.

Now, my Lords, with regard to the second head, I will try to be brief about that. I have said all I desire to say about the first matter, and may I go to the second head. May I, for my own assistance, summarise what I conceive here to be the allegation that is made against the Appellant? It is said because of what you had done, whether it was negligent or not, you had destroyed the pelvic floor and your first duty, therefore, as a medical man, using the knowledge which you had, was to repair the pelvic floor so as to prevent what the witnesses, I think, termed herniation,

so that when the patient stood up things which ought to have remained inside came outside, and the way to do it was by an operation, by sewing or by stitching. If you had done that you might have saved the patient's life, and in any event the exploration for the purpose of the operation would have shown you there was an injury to the bladder and the intestines, which had been crushed against the sacral promontory. It was derived from the evidence of her friends that she was at some time after the birth in a condition to stand an operation. Then it is said, lastly: It was your duty to take a second opinion. As I appreciate them, those are allegations of negligence which are made upon the second head. The answer made is this: The non-removal for the operation between July 24th and 28th was not a negligent thing at all; it was a carefully considered medical view. It is said in support of that view that to move the patient at any time after this event had occurred would have meant probably immediate death. It is said that there was no moment between the happening of the uterus giving way and the removal to the hospital when it was a wise and safe or proper thing to do. It is said the symptoms of peritonitis, the woman having died from peritonitis, and shock, were coincident with the moment of delivery; and with regard to drainage, it was suggested that the patient, having regard to the removal of the uterus and the position in which she was placed, had in fact the most effective and natural drainage that you could possibly have to get away the poisonous matters which might have infected the system. Then it was said of all the previous cases which are recorded everything in those cases pointed against the operation and in support of the very conduct which Dr. Bateman followed. In the case in 1912 of which Dr. Spilsbury spoke from personal knowledge, the patient died 40 minutes after removal. In the two cases spoken to by Dr. Banister for the Defence, one woman died before she reached the hospital and the other woman died 30 minutes after admission. Those are the answers which are made, speaking quite generally, with regard to the second head of negligence.

Mr. JUSTICE SALTER. How many requests did Nurse Cleak make to the doctor?

Mr. BIRKETT. The nurse made three requests, my Lord. She asked on the night of the 23rd when the child was delivered: Ought not she to go to the hospital? She asked on the Friday, the 25th, and she asked upon the Sunday, the 27th.

Mr. JUSTICE SALTER. Was she ever asked whether when she made those requests she thought that the woman could be moved?

Mr. BIRKETT. I am much obliged to your Lordship for mentioning that. Mr. Justice Shearman in his summing-up to the Jury put that point in favour of the Defence, that the nurse herself never thought that there was a moment when she was any better from the night when this thing first happened. It is an extremely important point. At page 30 of the transcript in Question 418 in Nurse Cleak's evidence there is this question: "You realise the question of moving this woman down four flights of stairs is a very serious matter?—(A.) Yes. (Q.) You say the doctor said to you when you said you thought she ought to go to a hospital, I am talking of the night of the 21st, 'I will see how she is in the morning and then send her away, she is not to be moved yet'?—(A.) Yes." That, as a matter of fact, was, as your Lordships perfectly well know, the view of the experts who were called for the Defence and who spoke in the very strongest possible way.

The LORD CHIEF JUSTICE. So far from being a useful step it would in fact have been a dangerous step?

Mr. BIRKETT. Yes, my Lord, it would. If I may say it now, my Lord, the two doctors who were called for the Defence—your Lordships will have read the

qualifications of those two gentlemen; they have tremendous experience—when the question was put to them what you would do in the like circumstances answered; I should do exactly what this Appellant did. Then when they were asked: Is there anything that you could suggest that he did do which he ought not to have done with regard to removal to the hospital? the doctors make answer: It would have meant in my view immediate death.

MR. JUSTICE SALTER. Sir Bernard Spilsbury said he thought she may have had just a chance.

MR. BIRKETT. Yes, my Lord, he said just a chance. I think, if I may say so respectfully, the view that was taken apparently by Dr. Spilsbury and Dr. Buchanan was this, that the uterus having been torn away and the ligaments having been torn away certain blood vessels were torn at the same time, and unless you did something either by stitching or sewing to deal with those blood vessels to prevent the possibility of toxic poisoning, the woman would certainly die. The answer made, as your Lordships appreciate, was that the bleeding stopped, and the evidence given was that the clotting might have been a very proper and natural thing to stop the bleeding. To leave her in that position so that she might have some chance of healing before being removed was not merely the most humane, but the wisest and most prudent thing to do.

THE LORD CHIEF JUSTICE. I understand one of the questions which you suggest under this fourth head is the question whether a professional man can be found to be criminally negligent for doing that which two heads of his profession swear they themselves would have done in the same circumstances?

MR. BIRKETT. I submit that, my Lord, and I am sure it will be understood that nobody in this Court could have a higher admiration for Sir Bernard Spilsbury than I, but he is a pathologist and not an obstetrician. It is put as strongly as this, my Lord: I myself with my knowledge and my experience would have done exactly the same. If you had done what Dr. Spilsbury said it would have meant death.

THE LORD CHIEF JUSTICE. Is it not material to look at the frequency or rareness of such a dilemma? Apparently the tearing away of the uterus is a very rare thing. Is a man to know or to be expected to assume that if that rare event happened then all risks must be taken and the patient must go to hospital?

MR. BIRKETT. No, my Lord, I should have submitted not.

THE LORD CHIEF JUSTICE. If it were a thing that happened every day other considerations might arise.

MR. BIRKETT. Your Lordships will appreciate that upon the last point your Lordship has raised it is again a substantial ground on which I rely for the misdirection of the evidence. The learned Judge told the Jury that that factor did not really matter. My learned friend took the extreme course of interrupting the learned Judge in his summing-up to point out what Dr. Banister said about that matter; but the learned Judge said it really did not matter. But it was vital to the defence that in this very rare occurrence in their view this man had done in that emergency everything that a practitioner could do. It is a matter upon which I rely with regard to the misdirection. Would your Lordships now look at page 61 of Dr. Spilsbury's evidence. At Question 769 he is asked: "If that is left, and no attempt made to repair it, what would be the result on the patient?" (A.) I think the inevitable result must be death either very shortly from shock and hæmorrhage, or at a later period, from the development of the infection, peritonitis.—(Q.) That is quite apart from the tear of the bladder, the rupture of the colon?—(A.)

Yes, quite apart from that. (Q.) If that would be the result if it was not attended to, what would it be the duty of a medical man to do?—(A.) To take steps to arrange for an operation as soon as possible afterwards. (Q.) This injury took place just after midnight on Wednesday, the 23rd July, early morning of the 24th July; would it have been the doctor's duty to have had an operation performed either there or at an hospital that night or when?—(A.) It would depend upon the patient's condition. She would, no doubt, be unfit for operation immediately afterwards, she would be in a state of collapse, but as soon as she rallied from that she ought to have been operated upon. (Q.) Can you form any opinion from the length of time she lived afterwards, and after the removal to the hospital, whether at any time after this injury she was in a condition to stand the operation?—(A.) It is very probable she was. I have no doubt in my own mind she was in a condition to be operated on from the account given of her condition by her friends. (Q.) She was admitted to the infirmary and a letter was written by Dr. Bateman saying: "On extracting the placenta I found to my surprise that the uterus came with it. Evidently the foetus had been expelled into the pelvic cavity some time previously, and the uterus had contracted, firmly, on the placenta." What do you say about that having regard to the evidence which has been given?—(A.) From what I have heard of the evidence I think it is clear the child had not escaped into the pelvis, because, as I have already said, there would have been signs of collapse as soon as that occurred. (Q.) 'She was very collapsed, she has been doing fairly well until the present, but is now in a bad way.' If she had been doing 'fairly well' up to the present, can you see any justification for not sending for the ambulance or the hospital authorities?—(A.) No." The only thing on that is that Dr. Spilsbury is forming the best view he can, but he relies upon those statements which are made by the husband and mother and Miss Lehoux that she seemed brighter, whereas he ignores entirely the more skilled evidence of the midwife of 37 years' experience, who was likely to know, and she says there was at no time any change between what happened on the night of the delivery and the day that she was sent to hospital. Your Lordships realise that she was sent to hospital. Dr. Bateman said: If I give her an anæsthetic she will die on the table. Now, my Lords, I propose to turn to the question of misdirection with regard to the evidence.

SUBMISSION OF MISDIRECTION WITH REGARD TO THE EVIDENCE.

Tuesday, Feb. 10th.

MR. BIRKETT. My Lords, there were two matters remaining with which I wanted to deal quite shortly. They were under two headings, the first being misdirection by the learned Judge, as to the evidence, and my last and final point, that the verdict was against the weight of evidence.

The first of those two matters, namely misdirection by the learned Judge on the evidence, I approach with some diffidence. I do not know whether your Lordships are familiar with the facts which are set out in the Notice of Appeal, but there are set out there, I think, fourteen separate heads upon which misdirection is alleged. I can spare your Lordships a good deal of time and trouble upon that, I think, by saying this, that the only importance that is, I think, to be attached to the allegations of misdirection on the evidence would be as to their possible cumulative effect.

THE LORD CHIEF JUSTICE. You may take it that we are aware of what was said in the summing-up.

MR. BIRKETT. If your Lordship pleases. Subject to that, I think the only matter to which I can draw attention, because we regard it as of some importance, is this: it is I think rather imperfectly expressed in No. 5: "The learned Judge told the Jury, upon a

matter of the gravest importance to the Defence, that the evidence of the doctors called for the Defence was of no importance. The injurious effect of this was heightened by the fact that the learned Judge persisted after the error had been pointed out." I think that is a little improperly worded, due probably to some little misapprehension; but there is a substantial point at line 260 of the summing-up, which your Lordships will find on page 146, about four lines from the top: "It is admitted that the coming away of the womb in the case of a childbirth is almost unknown. Dr. Spilsbury in his wide experience has only heard of it twice, and the doctor who was in charge of Queen Charlotte Hospital said 'I have had under my charge 60,000 cases and I have never heard of such a case,' and the other witness said he had not heard of such a case. Dr. Spilsbury said when it has happened before, in his experience the child has died at once. (Mr. Davis): Dr. Banister said he has two cases."

The LORD CHIEF JUSTICE. It was the mother who died?

Mr. BIRKETT. Yes.

The LORD CHIEF JUSTICE. Not the child?

Mr. BIRKETT. That is so, my Lord. I do not think that the child was mentioned. The child may have died, but it was the mother who was mentioned in the evidence.

The LORD CHIEF JUSTICE. It is not disputed that it was the mother who died.

Mr. BIRKETT. Yes. Then Counsel for the Defence says: "Dr. Banister said he had two cases"—and, of course, the Defence relied in the strongest possible way on the evidence of Dr. Banister with regard to that matter. (Mr. Justice Shearman): I think he said as regards turning the womb inside out; certainly at the hospital he said there had been no case, but at any rate it does not matter whether they heard of one or two cases, it is an extremely rare case and one of those where the experts differ." I think with very great respect that the learned Judge and learned Counsel for the Defence at that time were somewhat at cross purposes. The learned Judge was minded to point out I think in the interests of the prisoner that the situation that the prisoner had to deal with was an extremely rare occurrence, and his mind was solely centred upon that matter. Counsel for the Defence interrupted him to point out that there had been two cases, because of the enormous importance to the Defence of those two cases, which, in the submission of the Defence, justified entirely the line of conduct which had been pursued by the Appellant in this case, namely that the proper course of treatment was rest, and that if you moved the patient either to hospital or elsewhere, according to the recorded cases death was the almost certain and immediate result; and the matter which is complained of in the Notice of Appeal I think amounts to this, that there was, shall I put it, an inadvertent misdirection on the evidence, inasmuch as the Jury may very well have believed from the way that matter was dealt with that the evidence which had been called by the Defence through Dr. Banister upon so vital and important a matter was said by the learned Judge in that passage to be a thing of no account, inasmuch as it did not matter.

If I may take that as an illustration, and refer only to one more, the complaint, if it justifies so strong a term as complaint, which is made by the Appellant on this head is that in several matters in the summing-up there are, shall I say, inadvertent mis-statements which might have worked, and in the submission of the Defence did in fact work, greatly to the prejudice of the Appellant. The only other one I will mention is one which I think is numbered (ii.): "The learned Judge told the Jury that the removal of the womb was sufficient to support a conviction." On line 254 on page 145, if this is an accurate transcript, the learned Judge says: "Let me pass on to the second question.

The Crown first of all say there was gross negligence, and you will not find it unless you are quite satisfied of it, in pulling away the womb at all"—then the transcriber has put what I presume he intended for a dash—"in what he did before and in pulling it away." I do not apprehend that something is left out there.

The LORD CHIEF JUSTICE. It is undoubtedly a dash.

Mr. BIRKETT. I have two marks.

The LORD CHIEF JUSTICE. That is not the shorthand writer, that is the typewriter.

Mr. BIRKETT. Yes. I only mention it because it might very well have been that there was some word left out there. "The Crown first of all say there was gross negligence, and you will not find it unless you are quite satisfied of it, in pulling away the womb at all—in what he did before and in pulling it away. It is suggested by the defence nothing of the sort," and so on. The point about that is in my submission really rather important. Here was a Jury no doubt shocked and horrified at hearing of what actually did happen—that is, the removal of the uterus from a woman in childbirth; and I hope that I am entitled to say that an ordinary jury might very well and very naturally think "Why, the mere pulling away of the uterus at all in any circumstances was in itself a grossly negligent thing," being naturally ignorant of the fact that the placenta and the uterus had an edge which was, as I understand it, precisely similar, soft and thin and regular, so that to the touch there would be no distinction whatever. The submission on behalf of the Appellant on this point—

The LORD CHIEF JUSTICE. When I hear you say that, it occurs to me to ask: Is it not necessary to consider the various movements in that process? It may well be that the doctor might begin to pull away the edge of the torn uterus, believing it to be the placenta, but when he perceived, if the Jury found he ought to have perceived, the degree of force which was necessary to pull away the uterus, ought he not to have realised that he was not removing the placenta.

Mr. BIRKETT. With respect I should have thought that that observation was exceedingly just if in point of fact it was beyond contest that a very considerable amount of force was used.

The LORD CHIEF JUSTICE. Not beyond contest, but there was evidence to go before the Jury.

Mr. BIRKETT. Yes, there was evidence on both sides about that. The evidence for the Defence, I think, was that it was a natural mistake to regard the edge of the uterus as the edge of the placenta.

The LORD CHIEF JUSTICE. That is the beginning.

Mr. BIRKETT. Yes, that is the beginning. Now, my Lord, this is the question as it is put here: "The Crown first of all say there was gross negligence, and you will not find it unless you are quite satisfied of it, in pulling away the womb at all—in what he did before and in pulling it away." Now, my Lord, the submission I make to you there is that the Jury might quite naturally and reasonably have believed that the mere fact that the uterus was removed, however it was done, was in itself an act of gross negligence. The point I want to urge about it is that in my submission it was so natural a thing for the Jury to do that it was very, very important in the Appellant's interest that the natural danger upon that head should be guarded against by very careful and precise wording in summing up the evidence, and in this phrase "you will not find it"—that is the gross negligence—"unless you are quite satisfied of it, in pulling away the womb at all—in what he did before and in pulling it away"—as I said, I approach this matter of misdirection—

The LORD CHIEF JUSTICE. In your opinion might the Jury not have taken this view: Here was a woman

33 years of age, the mother of four children, and a doctor has pulled away the uterus?

Mr. BIRKETT. That was the danger to be guarded against, I think. I speak my own mind and not anybody else's in saying I am very afraid that the Jury might do that, and I think in my submission it would be an entirely wrong thing for them to do.

The LORD CHIEF JUSTICE. The question I am asking you is: Might the Jury not say that in fact, but might they legitimately do it?

Mr. BIRKETT. They might do it in fact, and I think probably did, but legitimately I submit they had no right whatever to do it. That is a point which I endeavoured to put some considerable time ago in the interests of the Appellant, that that was the precise danger to be guarded against on the first head of negligence. Here, if I may reinforce the points I make upon this alleged misdirection, the wording of the learned judge in this sentence, "pulling away the womb at all" having regard to the very natural view that the Jury might take, was a very serious misdirection in fact so far as the Appellant was concerned.

Mr. JUSTICE SALTER. I am not quite sure that I follow that. I understood your point yesterday to be that this Part I. ought to have been withdrawn.

Mr. BIRKETT. Yes.

Mr. JUSTICE SALTER. The learned Judge decided not to withdraw it, thinking there was some evidence on Part I. What is your complaint on that sentence?

Mr. BIRKETT. The complaint I make is this, that the sentence may have led a lay Jury to suppose that the mere fact that the womb came away at all in this doctor's hands was sufficient for them to find him guilty upon the first head, whereas in truth and in fact the real question was whether in the pulling away of the womb there was in fact negligence. It may be an unsubstantial point, but it seemed to me to be a matter which might be capable with a lay Jury of leading to great misunderstanding.

The LORD CHIEF JUSTICE. It is fair to add, is it not, that Dr. Spilsbury at any rate had said that he had known of similar cases?

Mr. BIRKETT. He had.

The LORD CHIEF JUSTICE. In the language you are using you are drawing rather fine shades of distinction, are you not? You use three different phrases: One is "pulled away," another is "came away," and the intermediate term which you now use is "came away in the doctor's hands."

Mr. BIRKETT. I was brought up in a school, my Lord, where language was intended to conceal one's thoughts, but certainly in this Court it is not my desire so to do. I suppose it is the voice of the advocate adopting the language which comes to his mind which is most favourable to the Appellant; but whatever the precise shade of meaning to be attached to any of the phrases, the point I make with regard to this matter is that there was here, in my submission, a very natural danger to be guarded against, namely, that in a case which would shock and indeed horrify the members of the Jury—because it has occurred to me in dealing with this matter last night that there probably was not a man on this Jury who at some time had not been in the position of that husband waiting outside the door hoping that all would go well—in a case such as this, that being so, the mere fact that this very dreadful thing had occurred might cause them to say, very reasonably: "It does not occur in the ordinary case, and it is due to the negligence of this man."

The LORD CHIEF JUSTICE. There are two statements there: First, "that it does not occur in the ordinary case," and "it is agreed on all sides that

it was an exceedingly rare event." That it was due to negligence is different.

Mr. BIRKETT. That, as I understand it, was a matter which was dealt with by the Judge, but in this particular phrase in my submission he is not putting the true issue to them—"you have to be satisfied that in the act of taking away the womb there was criminal negligence." He is saying here, "in pulling the womb out at all." As I say, that is the point that I make, and I do not want to labour it. That is all I propose to say with regard to the heading of misdirection.

The LORD CHIEF JUSTICE. On that point, assuming that it was a point proper to have been left to them, what ought to have been said, do you mind telling us?

Mr. BIRKETT. With some hesitancy, I submit that the proper direction—I say this with great diffidence—that the proper direction to the Jury on that matter was that after there had been put before the Jury quite plainly the difference between civil negligence and criminal negligence, the learned Judge should have said, "Now upon this first head of the case it is said here that the uterus was in fact pulled away. Now, members of the Jury, put entirely from your mind any thought of convicting the prisoner merely because the uterus was pulled away; that is not enough. It might be removed by a skilled man—it might have been in any event. You must put that from your mind to consider this question, whether at any stage before that uterus was pulled away some act—"

The LORD CHIEF JUSTICE. Or in the pulling of it away.

Mr. BIRKETT. Yes, my Lord, "or in the pulling of it away, there was some act, some omission, something blameworthy on the part of this man which could make you say: Had it not been for your blameworthiness this thing never would have happened. Until you can do that you must not convict the prisoner."

The LORD CHIEF JUSTICE. Suppose, to bind the thing, a hypothetical Jurymen says, "I do consider it, and I observe he pulled it away."

Mr. BIRKETT. Yes, "I observe he pulled it away." The hypothetical Jurymen in that event would be himself blameworthy in so far as he did not sit there as he ought in a judicial mind to look at the evidence.

Reported Cases of Similar Catastrophes.

Dr. Spilsbury knew of one case, Dr. Banister himself knew of two others, and although I cannot refer to it here, I have been spending some of my days recently in reading text-books on this matter, and amongst the medical profession it is not confined to the three cases; the thing does occur.

Mr. JUSTICE SALTER. Are those cases where the womb is accidentally taken from the body as in this case?

Mr. BIRKETT. They were in the act of childbirth, as in this case, as distinct from where it is taken away on purpose.

Mr. JUSTICE SALTER. They were not cases where the womb was expelled from the body in childbirth?

Mr. BIRKETT. No, not as I understood them.

Mr. JUSTICE SALTER. But taken by manipulation?

Mr. BIRKETT. Yes, in the act of childbirth, in every case of which I have heard after prolonged labour, and where in most cases there had been the operation of version in order to turn the child before manual traction.

The LORD CHIEF JUSTICE. Was not one of the

reported cases a case where the mother was suffering from prolapsus?

Mr. BIRKETT. Yes, in the reported cases. That, my Lord, is what I submit, and I end practically upon that head with regard to misdirection by saying this: I know it is an easy thing for Counsel standing here to say that the learned Judge at the trial ought to have said this and that and to have picked out a matter here and a matter there and to say that the cumulative effect of those matters is really very important. I appreciate how easy that is and how difficult it is for him to put the matter as Counsel would like it from the difficulty I have in putting my own argument here.

The LORD CHIEF JUSTICE. You have put your points very ably indeed, Mr. Birkett.

Mr. BIRKETT. Thank you, my Lord. The statement I make upon that is that if these matters are taken into view in this rather extraordinary case (because I think everybody will concede that this is a very extraordinary case) these statements of misdirection to which I have drawn attention were such as to influence a Jury most materially on this particular matter. Now, my Lord, I come to the last point I have to make: It is a common rhetorical device, but with sincerity I put before the Court this—and perhaps the point I am now going to make is the sum of all the points which I have been endeavouring to make yesterday and to-day—the point is this: If you look at this case from every aspect and from every point of view, the statement can be made, and I make it, and I hope to make it with great force, that the final conclusion in this matter is that the verdict is against the weight of evidence, is unreasonable, and cannot be supported.

The Evidence of Expert Witnesses Recalled.

I do not want again to summarise or to review the facts, but I do desire to call attention to some of the answers given by the two expert witnesses for the Defence. Your Lordship will find the evidence of Dr. Banister at page 76. Your Lordship will see that he is a Doctor of Medicine, a Member of the Royal College of Physicians, a Member of the Royal College of Surgeons, London, a Member of the Royal College of Physicians, Edinburgh, of Harley-street, an Obstetric Surgeon and Consulting Surgeon to Queen Charlotte Hospital. He is also an Assistant Obstetric Physician and Lecturer on Obstetrics at Charing Cross Hospital. He is Surgeon to the Chelsea Hospital for Women, Consulting Obstetric Surgeon to Northwood Memorial Hospital, the Passmore Edwards Hospital, and the Florence Nightingale Home, and Examiner to the Central Midwives Board. Those are the qualifications of Dr. Banister.

The LORD CHIEF JUSTICE. And 15 years' actual experience in obstetric practice?

Mr. BIRKETT. Yes. I do not suppose it is a conclusive test, but I think the witnesses for the Defence on the precise point at issue were more qualified to speak than the witnesses called for the Prosecution. At any rate, there are the qualifications. At Question 915 he says that he has read Dr. Bateman's evidence given before the Coroner, and in reply to the next question he says that he has heard the evidence given at the trial. Then at Question 919: "(Q.) I want to ask you this first: In your own practice how many cases have you known of the uterus being removed in the course of parturition?"—(A.) Only two. (Mr. Justice Shearman.) Two besides this?—(A.) Yes, two besides this. (Sir E. Marshall Hall.) Was any operation done in either of those two cases?—(A.) No. (Q.) Why not?—(A.) The first case that I saw was dead when she reached the hospital, and the second died within half an hour of her admission. (Q.) You have heard Sir Bernard Spilsbury's evidence in which he said the woman had a chance; would you accept that or qualify it?—(A.) I should say

that her chance was so small as almost to be disregarded, and that it would be without probability that she would recover. (Q.) Will you put yourself in this position for one moment, the position of the doctor, the prisoner here, after he has discovered, according to the evidence, that the uterus has come away with the placenta. You have heard all the evidence about the collapse, and would you yourself have taken the responsibility of removing her to a hospital for an operation then?—(A.) I should have forbidden her removal. (Q.) Whatever chance she had of life in your opinion would it have been increased or diminished by such a removal?—(A.) I think her chance of life would have been wholly removed. (Mr. Justice Shearman.) Do you mean she had any if she was alive?—(A.) I think you can say they have a chance so long as they are alive. (Q.) Assuming you have got ruptured arteries in the inside and intestines not sewn up, I can quite understand you saying it was hopeless, it was no good removing her, but I cannot understand that you could have left a woman like that in the belief that she could survive and recover." That is a question by the learned Judge which I think puts very concisely the main point which was alleged by the Prosecution upon this second head. "Do you suggest she could revive and recover without having something done to her to sew her up?"—(A.) I have not suggested that. (Q.) I understand you to say that the chance of recovery was practically nil?—(A.) Death was." I do not follow that, but that is the answer given.

The LORD CHIEF JUSTICE. "Death was certain," I suppose.

Mr. BIRKETT. Yes, I suppose he means "Death was certain." Then he is asked: "I thought you said the contrary?"—(A.) I said I would forbid her being removed then. (Mr. Justice Shearman.) I did not understand that. (Sir E. Marshall Hall.) Do you agree with Sir Bernard Spilsbury that probably there was a period between Wednesday midnight and 8 o'clock on the following Monday, when she might have been removed with the probability of a successful operation being performed?—(A.) Change 'probably' to 'possibly' and I agree. (Mr. Justice Shearman.) I think they do agree there was just a possibility?—(A.) Just a chance. (Sir E. Marshall Hall.) Have you heard anything in the evidence which would lead you to say that between Wednesday midnight and Monday at 7.30 there was any more favourable moment at which she might have been removed?—(A.) No. (Q.) Who would be the best person to judge as to the desirability of her removal at an intervening period of time?—(A.) I should say the doctor in attendance. (Q.) You have heard the evidence of the husband as to the pains?—I do not think I need trouble about that; he is there beginning to deal with complex as against transverse presentation. On page 81, at Question 954, he is asked: "Do you agree with Sir Bernard Spilsbury that in all probability if the presentation was such as we are now describing the child was in fact dead, and dead for some time?" That was the head and feet and cord all presented together. His answer is: "I do not know that we can say that with certainty from the evidence. (Q.) Is there anything in that form of presentation that excludes the possibility of a living foetus?"—(A.) I should say it is almost impossible to obtain a living baby. (Q.) A delivered baby I agree, but I am asking you whether the foetus was in fact dead when the presentation was diagnosed?—(A.) It is more likely to be dead than alive, but I do not see that you can say it is either. (Q.) Supposing that presentation and no manipulative interference, what do you say, might you get a rupture of the uterus?—(A.) Yes." That is the point which Mr. Justice Salter raised yesterday as to the injuries being consistent in certain cases with natural labour. (Q.) Will you explain to my Lord and the Jury what you mean by that and why you say it?—(A.) It is a well-known clinical fact

that the uterus can rupture in the course of a perfectly normal labour. I myself have seen three cases in which the uterus has ruptured while the patient has been lying in bed and apparently being a perfectly normal labour. The most common cause of rupture of the uterus is, I think, the use of some manipulation to effect delivery during the time that the uterus is very tightly contracted. (Q.) I want you to tell the Jury how that acts?—(A.) The way in which a rupture takes place is that the head of the child—usually this manipulation is to deliver the baby by the feet, and in order to deliver the baby by the feet the head has to be pushed up out of the way, and sometimes during that pushing and pulling down the head is pushed through either the side of the uterus or the junction between the uterus and the vagina, and I believe when such an accident as that does occur that it is only chance which decides how wide such a rupture is going to be. (Q.) If such a rupture had in fact taken place can you say, would it increase the probability or the possibility of the uterus coming away with the placenta?—(A.) The wider the rupture the less the attachment of the uterus, and the less attachment the greater the chance of the uterus coming away. (Q.) The nurse's evidence is that in removing the placenta he gave it a sharp pull. Would that, in your opinion, be a possible cause of removing the uterus with the placenta?—(A.) I think it would be enough to separate what attachment was left. (Q.) In your opinion is it possible that a medical man might, in removing the placenta, remove the uterus and not be aware he had in fact removed the uterus? (A.) I think it is quite conceivable. (Q.) Would his power of discrimination be increased or reduced by the fact that he had been spending a whole hour in procuring delivery of the child?—(A.) It would be very much reduced. (Q.) We heard that the child was brought out feet first, dead; does that strengthen or weaken your theory with regard to the actual presentation in this particular case?—(A.) I think it strengthens it, Sir. (Q.) There is a statement here that there was an injury to the bladder and an injury to the rectum. Now as to the injury to the bladder, it is said that that probably had been caused by some instrument having caused the injury, what do you say about that?—(A.) In one of the comparable cases that I have seen, in my experience the rupture did run right across the top of the bladder. (Mr. Justice Shearman.) Do you mean it is the touching by the hands or pressure which breaks it?—(A.) No, as the head gets in between, and having started the tear it runs across the front and pulls the peritoneum with the bladder attachment. (Sir E. Marshall Hall.) Consequential?—(A.) Yes. (Mr. Justice Shearman.) The head of the child pushed up against it causes it to split?—(A.) Yes. (Q.) What is the bladder?—(A.) It is comparatively thin with a certain amount of muscle, and inside that a mucous membrane, and it can be very easily torn. (Sir E. Marshall Hall.) Has the placenta got an edge to it?—(A.) Yes. (Q.) Is the placenta something flat; what does it look like?—(A.) It weighs somewhere about a pound. It is about that size round and it is about that thick at the edge and that thick in the middle (describing). (Mr. Justice Shearman.) It is a Latin word which means an ordinary cake, a flat cake. (Sir E. Marshall Hall.) If there was a tear in the uterus would it be possible to mistake the edge of that tear for the edge of the placenta?—(A.) Yes, they would both be soft and they would both be irregular. (Q.) If that did happen and pressure was put on the edge of the torn uterus instead of the placenta what would you expect?—(A.) The uterus would come away. (Mr. Justice Shearman.) You think when he was pulling at the placenta he caught hold of the tear of the uterus and took it for the placenta and gave it a tug?—(A.) Yes, I think what he thought was the placenta was not the placenta, it was the edge of the uterus. (Sir E. Marshall Hall.) Is that quite a reasonable explanation of how this uterus came to be taken away?—(A.) I think so, yes. (Q.) Do you agree with Sir Bernard that great force would have to be used under those conditions to tear the uterus?—

(A.) No, I am afraid I do not. (Q.) From your own personal experience what is your own view with regard to the amount of force?—(A.) I do not think it would be any more than might reasonably be used in separating a placenta from a uterus. If you mistake the edge of the uterus for the placenta, an equal amount of force might quite easily separate the whole organ." That, subject to the cross-examination by my learned friend of the doctor, was in my submission absolutely overwhelming evidence for the Jury.

The LORD CHIEF JUSTICE. I see that in the question which was put to the Witness the expression which was used was that according to the nurse he pulled it sharply. That is at Question 961. The words are: "He gave it a sharp pull."

Mr. BIRKETT. Yes.

The LORD CHIEF JUSTICE. That is not exactly what she said. Her evidence is to be found at Question 209, on page 15. She is asked: "Describe that to us, will you? How did he do that?" and her answer is: "He pulled it rather sharply."

Mr. BIRKETT. Yes. On the other hand it would also be pertinent to remember that when the nurse was asked the general question: Did he do everything that a doctor ought to do, the nurse made answer, Yes, he did.

The LORD CHIEF JUSTICE. Yes, that is so.

FINAL ARGUMENT FOR THE APPELLANT.

Mr. BIRKETT. My submission upon that evidence which I have just cited is that it was absolutely overwhelming evidence of the highest possible kind on this very difficult case, which completely exonerated the Appellant from any charge of negligence; and when it is remembered, although I do not propose to read it, that Dr. Roberts, of equally high standing, agrees in substance with the evidence which is given by Dr. Banister (as will be seen on page 97), I do submit, and with some earnestness, that having regard to the responsible and honourable duties which fall to the members of the medical profession, called upon as they are to confront emergencies at all hours of the day and night, and who give all their time and skill in those circumstances, to say of a man, when an untoward thing like this happens which may be said to be almost unknown in the history of the profession, to speak quite generally, and when two of the most eminent physicians and surgeons which this country knows come and say in terms, and justify it, "I should have done what this man did, and to do other was to cause immediate death"—to say that that man shall be found guilty of manslaughter would be, to adopt the words which were used at the end of one of the judgments which I read yesterday, to place the members of that profession in a very hazardous situation which would deter men from entering the medical profession.

Those are the points which I venture to submit on behalf of this Appellant, and I submit that on any ground I am entitled to succeed, but that these last points which I have ventured to put, namely that having regard to the nature of the evidence given the verdict so given was against the weight of evidence, the verdict was unreasonable and against the weight of evidence, is a submission which in this Court ought to prevail.

Your Lordship will remember that last time at the application for leave there was a further application for leave to call further evidence. Your Lordship will remember the terms in which your Lordship addressed me at that time, which gave me a discretion in the matter with regard to calling certain evidence. I have in Court a very distinguished gentleman indeed of very great experience in this class of case, who is anxious to give evidence, and of course if the Court thought fit I should be glad too that he should do so;

but I am not able to say that that is evidence which was not available to us at the trial. It is evidence, if your Lordships would allow me to say so, of the very highest kind, which would support and confirm in detail the evidence which has been already given. In those circumstances, having regard to the terms in which your Lordship addressed me, I do not feel that I can press this application. The doctor, who is here now, and sitting by me, would be very glad to place himself at the service of the Court if the Court thought fit.

THE CASE FOR THE CROWN.

MR. ROOME. My Lord, the case for the Crown was, in the language of Lord Ellenborough in the case of *The Queen v. Williamson*, that the prisoner had been guilty of criminal misconduct arising either from the grossest ignorance or the most criminal inattention—

The LORD CHIEF JUSTICE. From what are you reading?

MR. ROOME. From the Judgment of Lord Ellenborough in the case of *The Queen v. Williamson*.

The LORD CHIEF JUSTICE. In a passage already cited?

MR. ROOME. Yes, my Lord. The two divisions into which this case falls rather illustrate the two branches of the negligence to which Lord Ellenborough drew attention. First of all it was said that to remove the uterus at all may be itself an act of gross negligence arising from the grossest ignorance, and also from gross carelessness. In other words, owing to the extreme rarity of such a tragedy occurring, it was put before the Jury on behalf of the Crown that they might find that the prisoner must have either been grossly ignorant or extraordinarily careless in not discovering before he had pulled out the uterus that it was not the placenta, as he had at first imagined that he had caught hold of, but owing to the increased resistance that the uterus would have over the placenta, he ought to have inferred that it was the uterus, or at any rate he ought to have paused for reflection, and if he had so paused and reflected, he could have checked himself, instead of going on to pull "rather sharply," and to use, in the opinion of the witnesses for the Crown, the very considerable degree of violence which must have been necessary to remove the uterus.

The LORD CHIEF JUSTICE. So far as I see on reading this transcript, there was no evidence in detail as to the difference between the physical surroundings of the placenta and of the uterus. The placenta is something which lies there, and may have to be pulled away, is it not?

MR. ROOME. Yes, my Lord.

The LORD CHIEF JUSTICE. But what is it that holds the uterus in position?

MR. ROOME. There is some evidence upon that. Your Lordship will find it in the cross-examination of Dr. Roberts. I questioned him upon that point.

The LORD CHIEF JUSTICE. Is that on page 97?

MR. ROOME. Yes. That was his evidence-in-chief.

The LORD CHIEF JUSTICE. The placenta was something which was intended to come away?

MR. ROOME. Yes, my Lord.

The LORD CHIEF JUSTICE. The uterus is not. What is it that holds the uterus in position?

MR. ROOME. There are several things which your Lordship will find at Question 1194 on page 106: "I want you to help me if you will in showing what

is involved by the uterus being removed in the circumstances in which it was in this case. What has to go?—(A.) What has to go? (Q.) Yes?—(A.) The floor of the pelvis first of all, and secondly, the cellular tissues which support the neck of the womb. Do you want me to go on? (Q.) Yes, please. —(A.) I do not think there is any more to say than that. (Q.) I suggest to you more than that must go before the uterus can be removed?—(A.) Yes. (Q.) Tell my Lord and the Jury what must go?—(A.) Very little. There must be a thin layer of the peritoneum and the very feeble peritoneal additions which are called ligaments. (Q.) They are what are called the broad ligaments?—(A.) Yes, the broad ligaments. (Q.) And they support the uterus on each side?—(A.) No, sir; they do not support it. (Q.) What are they for?—(A.) I do not quite know. (Q.) Are they useless, in your opinion?—(A.) Almost, except to convey the blood-vessels to the uterus."

The LORD CHIEF JUSTICE. This, as I understand, is the cross-examination of the doctor called for the Defence?

MR. ROOME. Yes, my Lord.

The Attachments of the Uterus.

The LORD CHIEF JUSTICE. Was there evidence on behalf of the Crown showing the strength and the variety of the different supports which retain the uterus in position?

MR. ROOME. I am afraid not. Sir Bernard Spilsbury, when he was in the Box, was not asked that question, but, of course, in putting the suggestions which I did put to Dr. Roberts, I was acting on instructions. Sir Bernard was sitting in front of me. There was no actual evidence to support the suggestion which I made that these ligaments are very strong, and that, in fact, they exist to hold the uterus in position, because they are—

The LORD CHIEF JUSTICE. The witness denied that.

MR. ROOME. He denied that they are strong.

The LORD CHIEF JUSTICE. But he said that if they did not support, he did not know what they did. Nature does nothing in vain.

MR. ROOME. That is what I was trying to suggest to him, but he would not accept it.

MR. JUSTICE SALTER. Can you refer us to the passages, if there are any—I will take the evidence of the Prosecution first—in which Dr. Spilsbury or Dr. Buchanan (I think it was) expressed any opinion that the removal of the uterus in the circumstances of this case was inconsistent with average care and average skill?

MR. ROOME. At Question 755 there is some evidence on the point. It really begins at Question 752, in the evidence of Sir Bernard Spilsbury.

The LORD CHIEF JUSTICE. Of course, one knows that as controversy develops, and as evidence is given, the perspective of a case changes, and quite properly changes, but when the case began, was it a cardinal point in the case for the Prosecution at its outset that here was the uterus pulled away, and that in itself was enough?

MR. ROOME. No, my Lord.

The LORD CHIEF JUSTICE. I thought not, or his evidence-in-chief would have been somewhat different from what it was.

MR. ROOME. Yes, my Lord. I was not present when the case was opened, but I had seen my learned friend, Mr. Percival Clarke, the evening before; and the case for the Prosecution originally was: concede every allegation of negligence that possibly can be

involved in removing the uterus, found no criminal charge upon that; it is the subsequent conduct of the Defendant which we say amounted to such criminal inattention as to be manslaughter.

The LORD CHIEF JUSTICE. And then the Defence counters, or seeks to counter, that by saying: "Yes, but in the events which have happened, it was not an acceleration but a retardation of death to keep this unfortunate mother in her bed." Then the Prosecution begins to pay a new attention, or a new degree of attention, to the pulling away of the uterus?

Mr. ROOME. Yes, my Lord; I think it was rather upon—I will not say the invitation, but upon the suggestion of the learned Judge that there were both aspects to be considered; but much more stress was laid, and laid by me (because my learned friend had left by that time) in my final address to the Jury, on the second aspect of the case, than on the first.

The LORD CHIEF JUSTICE. That is to say, you ended as you began?

Mr. ROOME. Yes, my Lord. On page 59, at Question 752, Mr. Percival Clarke, in examining Sir Bernard Spilsbury in chief, asks: "Here we know that when removing the after-birth he removed the uterus too?"—(A.) Yes. (Q.) Can you imagine how that came to be done?—(A.) Only by seizing the wall of the uterus and pulling upon that instead of the after-birth, and that would probably only have happened if there were already a tear in the wall of the uterus which would enable it to be seized. (Mr. Justice Shearman): You are suggesting that putting his hand in to get out the after-birth he caught the tear of the uterus and pulled that instead of the after-birth?—(A.) Yes, my Lord. (Mr. Percival Clarke): Would that require force to dislodge it or not?—(A.) Oh, yes, very considerable."

The LORD CHIEF JUSTICE. That is your strong passage on that point?

Mr. ROOME. Yes, on that point; but there is also a passage in the evidence of Dr. Buchanan—

The LORD CHIEF JUSTICE. Somebody else said, "A lot of force."

Mr. ROOME. Yes, my Lord. At Question 628 Mr. Percival Clarke asks Dr. Buchanan: "In the ordinary course how is the uterus kept in its position in the living body?"—(A.) There are several physiological factors operating in that case, but the principal physical one is its attachment to the broad ligaments, its inclusion in the broad ligaments. I should not say attachment. I think inclusion is the proper term. It is suspended by the broad ligaments. (Q.) To what are those attached?—(A.) The broad ligaments are like a curtain hung across the pelvis and they are attached to the bony wall on either side of the pelvis; it is suspended in that way. (Q.) Is the uterus suspended firmly in its position in that way or not?—(A.) It is normally. (Q.) In order to dislodge it or remove it would much force or little force be required?—(A.) Well, it is only personal opinion, but I should say a lot of force. I have never known it to be removed." Then a little later he said what my learned friend said yesterday: "(Mr. Justice Shearman): It is a very remarkable thing to pull out the uterus. I am not saying whether it is wrong or not, but it is a very remarkable thing"; and the witness says: "As a technical point it is beyond my comprehension altogether." Upon that it was suggested by the Crown that the mere removal of the uterus in those conditions might, if the Jury chose so to regard it, be an act of gross negligence, as showing the grossest ignorance of what the doctor was doing; and the Prosecution said that the conduct of the accused shows clearly that he thought it was, because you find that he does not inform the relatives of what has happened; you find that he

impresses upon the midwife to tell nobody—not only that she should not tell the relatives, but that she should tell nobody; you find him taking the uterus home and leaving the placenta behind, so as to indicate that an ordinary delivery had been brought about; and you find that he takes no steps to go and inform anyone at the hospital, or anybody holding a somewhat higher position than he holds in the medical profession.

The LORD CHIEF JUSTICE. Is not that a rather perilous line of argument, if the evidence is weak to show that the pulling away was negligent; because these things might come in, either 1, 2, or 3, but especially 1, 2, and 3 together, to supply the make-weight, and make the Jury say: "Well, he has shown by his conduct that he thought it was negligence."

Mr. ROOME. Yes, my Lord.

The LORD CHIEF JUSTICE. Would that alter the character of that which had been done?

Mr. ROOME. No, it would not alter the character of it, but if the Jury were of the opinion: "Well, this man himself must have thought that he had been grossly negligent—"

The LORD CHIEF JUSTICE. But suppose that that is a *non sequitur*, and that what he did was consistent with quite other views and quite other motives; what you get then is confusion of mind supplementing imperfect evidence, and producing a proof.

Mr. ROOME. It was for the Jury to say, and I should think that they were entitled amongst other things to take into account the Appellant's own conduct.

The LORD CHIEF JUSTICE. Of course they were.

The Patient's Chances of Survival.

Mr. ROOME. Much more stress was laid upon the second branch of the case. It was said that this was no error of judgment, but that this Appellant expected that woman to die. He admitted that himself, and he said that if he had come next morning and found that she had died, he would have given a death certificate, and in that case nobody would ever have known what he had done.

The LORD CHIEF JUSTICE. Again, supposing that were so, would that have altered the intrinsic nature of what he had done or omitted?

Mr. ROOME. No, but he supplied the motive for what the Crown said was his wicked and criminal inattention in leaving her there and doing nothing for four or five days, and not giving her that one slender chance of recovery to which she was entitled.

The LORD CHIEF JUSTICE. But unless there is to be a begging of the question, the question still remains: Was there criminal and wicked inattention? If there was not, you need not trouble about the motive of it.

Mr. ROOME. No, my Lord, but on the evidence the Crown said that there was first of all what he omitted to do, that is to say he omitted to do something which both the eminent doctors who were called for the Defence said they would have done: He omitted to make any attempt to insert a drainage-tube into this woman's body; they both said they would have done that; he omitted to take a second opinion; and they both said that that was desirable. All that the Appellant did was to mention what had happened to his locum-tenens when he returned to his consulting room. He made no attempt to remove the woman to hospital; and no attempt, if he thought that that was dangerous—

The LORD CHIEF JUSTICE. He said that that was a good thing.

Mr. ROOME. Yes, he said so.

The LORD CHIEF JUSTICE. He said that he prevented her from dying earlier by not removing her to the hospital.

Mr. ROOME. Yes, my Lord. The Prosecution said: "No, he did that in order to prevent anybody finding out what he had done." If he had thought that she was in too dangerous a condition to remove to hospital, when he found on the next day, and the day after, and the day after, that she was still alive, and according to the evidence of the relatives a little brighter, and according to the letter which he himself wrote to the hospital authorities, doing fairly well, then if his object had been to treat his patient in the best way, and if he were really trying to do his best, he might have brought a surgeon to her bedside to see whether or not in the surgeon's opinion she was fit to be operated upon in that room, if she was not well enough to be removed to hospital.

Mr. JUSTICE SALTER. Supposing that he had put in drainage-tubes, and had got a second opinion, and had had her taken to the hospital, what was the evidence that her life would have lasted longer than if did in fact last?

Mr. ROOME. The evidence upon that first of all will be found at Questions 854 to 862. Of course it was hypothetical evidence. The evidence was that, in the opinion of those medical men, there would have been just a chance.

The LORD CHIEF JUSTICE. And of course it was evidence after the event.

Mr. ROOME. Yes, my Lord. Question 854 is a question put to Sir Bernard Spilsbury: "You were asked a question by my learned friend, and you were asked whether you could say there was a period between then and the following Monday when she could have been operated on with safety?"—(A.) I do not think I said 'with safety'; I would not go so far as that. (Q.) She might be operated on?—(A.) Yes. (Mr. Justice Shearman.) I have got the words 'As far as I know it is a possibility.' (Sir E. Marshall Hall.) I thought he said that it was possible she might be in a fit condition. (Mr. Justice Shearman.) 'You must take steps to arrange for an operation as soon as possible after and it would depend on the patient's condition. So far as I can estimate she rallied sufficiently to permit of an operation.'"

The LORD CHIEF JUSTICE. Does that mean, to permit of a successful operation? One hears so often that the operation was perfectly successful, and the patient died.

Mr. ROOME. To permit of the operation which is the patient's one chance of life. If she is left as she is, with blood-vessels torn, the rectum ruptured, the bladder ruptured, impurity pouring into the peritoneum, death is certain. It is a question only of days and probably hours, but death is certain and inevitable. The one chance—a very slender one, but the one chance of saving her or prolonging her life—is to have an operation, which may or may not be successful.

The LORD CHIEF JUSTICE. Of course that statement involves a certain view of the facts. Another view was presented, namely that in the circumstances of this case, and in the physical posture in which the patient was lying, she was getting in fact at least as effective drainage as she would have artificially got.

Mr. ROOME. That was the evidence of the Appellant himself, but of no other witness.

The LORD CHIEF JUSTICE. All I am saying is that the proposition which you mention does not proceed upon admitted postulates.

Mr. ROOME. As far as the drainage proposition goes, it proceeds upon the evidence of the two witnesses who were called for the defence; and it was their proposition—the proposition of both of them.

Mr. JUSTICE SALTER. You have to prove, not that negligence may have accelerated her death, but that it did.

Mr. ROOME. Yes, my Lord.

The LORD CHIEF JUSTICE. In all this, if I may say so, exceedingly interesting and quite ingenious controversy, what becomes of proving beyond a reasonable doubt?

Mr. ROOME. It is for the Jury to say. When the Judge has ruled that there is evidence to go to the Jury, and they have evidence on the one side and on the other, is it not for them to say whether they consider it proved beyond all reasonable doubt?

The LORD CHIEF JUSTICE. Yes, it is for them to say, and then it may be for others to say whether they have reasonably said.

Mr. ROOME. In addressing the Jury I urged them not to convict this man unless they were absolutely driven to it by the weight of evidence. The case for the Crown was that they were not trying to snatch a verdict, and it was miles away from any question of error of judgment.

The LORD CHIEF JUSTICE. Nobody supposed for a moment that you would ever dream of snatching, or think of attempting to snatch, a verdict. No such thing is suggested.

Neglect to Obtain a Second Opinion.

Mr. ROOME. But if I may say so, this case was put particularly high for the prosecution. It was put: "Unless you think his conduct was so wicked that you are driven to find that he gave the grossest inattention to this unhappy woman, do not convict him." What impressed the Jury was the callous neglect, if I may put it in that way, shown by the Appellant in taking the uterus home with him, and not informing a single brother practitioner who might have been in a position to come and help, as it is common knowledge any doctor would. It is true the Appellant said that in Deptford doctors would not help one another without fee, but in my submission any doctor on being told of a terrible case like this having occurred, would have come at any hour of the day or night to that woman's bedside in order to see whether something might not be done for her; but the Appellant concealed from everybody who might be in a position to give help or advice what had really taken place, and then when he is being pressed, and the woman is getting worse after having been a little brighter, and he is pressed by her husband to send her away, he destroys the very foundation of his now alleged reason for keeping her there, namely that he thought she would not have been able to stand the shock, and when she is weaker he yields to importunity and sends her to the hospital.

The LORD CHIEF JUSTICE. I put to you a mere hypothesis following upon what you have said: Suppose that at that last minute of the eleventh hour he had still refused to let her go to the hospital, would your criticism have been less or more severe?

Mr. ROOME. His conduct at least would have been consistent, and one might be more disposed to accept his view that he did not send her because he thought it would be in her interest to leave her where she was. The prosecution did not for a moment accept his story. We did not accept that he had been consulting the interest of his patient. Our case was that having committed an unheard of, or practically unheard of, blunder, in the confinement, he then took every step in his power to conceal it, and that that was evidenced

by the whole of his subsequent conduct; and from the Jury having convicted him at all, they must have found that.

The LORD CHIEF JUSTICE. If that is an accurate representation of the case for the Prosecution, the foundation of it was that he had made a colossal blunder in pulling away the uterus, and that the rest of what happened threw light upon the colossal nature of that blunder; but that, I understand, was not the way in which the case was put at all.

Mr. ROOME. Yes, my Lord; perhaps "blunder" was the wrong word; I will say a colossal disaster—having done something at which he was appalled; because he said to the midwife, "What have I done? What shall I do now? I had better wrap it up and take it home." He was so appalled to think of what he had done—namely, having removed the uterus. No doubt he had never heard of such a thing having been done, but being appalled, being frightened, and thinking of his own position if this were found out, the case for the Crown was that he took every step to conceal it, and that in doing so he denied to this woman the one chance, although a slender chance, which she had; and that was the view which the Jury accepted in finding him guilty, because that was the way in which the case was presented to them on behalf of the Prosecution. Then when he writes to the hospital: "She has been doing fairly well, but is now in a bad way," he was expressing his own view. He says that she had been fairly well up to then, and if she had been fairly well up to then, what excuse was there for not sending her to the hospital long before she was in fact sent, or for not having some surgeon to her bedroom to see if he could operate upon her there? It was consistent in my submission only with his desire to hush this up for as long a period as he possibly could. It was not until he was driven to send her to hospital that he sent her. That being the case, and there being evidence to support it, the Jury had, of course, the great advantage of a most powerful speech from my learned friend Sir Edward Marshall Hall. It was a Jury of men only, because my learned friend had challenged all the women who originally were empanelled. No one could have had a fairer trial, and after what I submit was the most careful summing-up—

The LORD CHIEF JUSTICE. I do not follow that. I hear you say that; but your last remark seems to suggest that it could not possibly have been an advantage to the Appellant to have women on the Jury. You may be right, but I can imagine that it might be an advantage.

Mr. ROOME. I said my learned friend challenged them. It may have been an advantage, but he evidently did not think so. After what I submit was a most careful and accurate summing-up, the Jury convicted this man. Upon that I submit that there was abundant evidence to support that conviction if the Jury accepted it, and if the Jury took the view which was urged upon them on behalf of the Crown.

Mr. JUSTICE SALTER. The case against the accused, put in that way, is hardly negligence really, is it? I am not saying that that matters, but your case is not that he was ignorant or that he was careless, but that he concealed what he ought to have disclosed in his own interest or in the interest of the patient.

Mr. ROOME. Yes, but culpably and wickedly neglecting the patient—what Lord Ellenborough described as the most criminal inattention. It was put in that way; the most criminal inattention, desiring to shield himself.

The LORD CHIEF JUSTICE. Do you mean this, that he committed a blunder in taking away the uterus in the belief that he was taking away the placenta? So far, blunder; having committed that blunder he then proceeded not to seek to remedy the effects of the blunder, but to conceal the fact of it?

Mr. ROOME. Yes, my Lord.

The LORD CHIEF JUSTICE. That is your case?

Mr. ROOME. That is how it was put.

The LORD CHIEF JUSTICE. Must you not go a step further and say: and by reason of that concealment he accelerated the death of the patient?

Mr. ROOME. Yes, my Lord; and that was one of the points upon which the learned Judge specially directed the Jury, that they must be satisfied that the death was caused or accelerated—

The LORD CHIEF JUSTICE. That concealment amounted to inattention which was negligence, and that negligence accelerated the death?

Mr. ROOME. Yes, my Lord. While no one can say that the woman might not have died had she been removed to hospital the next day or the day after—she might not have stood the removal—yet there was evidence that an ambulance could easily have been procured, that a stretcher could have been sent up, and that she could have been carried down those stairs and taken in the ambulance and removed to hospital. There was the chance, at any rate, that something might have been done to prolong her life. On the other hand, it may have been that she would have lived no longer; but the Jury, I submit, are entitled to infer that her death was accelerated by leaving her where she was; in other words, they did not entirely accept the evidence of the two distinguished experts, who were not present, of course, and could not have been present, and never saw the woman during her life or at her death, but who came forward with theories which in their view would assist the Jury to arrive at a conclusion favourable to the accused.

THE CONVICTION QUASHED.

The LORD CHIEF JUSTICE. The Appellant, Percy Bateman, was convicted at the Central Criminal Court for manslaughter, and was sentenced to six months' imprisonment in the Second Division. He now, by leave of the Court, appeals against that conviction and that sentence. The Court is of the opinion that the appeal ought to be allowed and the conviction quashed. In view, however, of the importance of some, at any rate, of the questions which are raised, we propose to consider our judgment and to deliver it at a later day. Meantime, the Appellant is discharged.

Should be read by all members of the Clerical and Scholastic Professions.

London: John Bale, Sons & Danielsson, Limited, 83-91, Great Titchfield-street, Oxford-street, W. 1.

TWO GOOD BOOKS PUBLISHED BY SAUNDERS

Kolmer's Infection, Immunity and Biologic Therapy "is so well known to all practical pathologists and bacteriologists that, once the fact that a new edition has appeared and that it fully comes up to the standard of all its predecessors has been noted, little remains to be said."—THE LANCET.

By JOHN A. KOLMER, M.D., Dr. P.H., Sc.D. (Hon.), Professor of Pathology and Bacteriology in the Graduate School of Medicine University of Pennsylvania. Octavo volume of 1210 pages, with 202 original illustrations, 51 in colours. New (3rd) Edition. Cloth, 60s. net.

Stevens' Practice of Medicine: "Dr. Stevens has courageously followed in the footsteps of his old master, Sir William Osler, and of other famous writers, and has produced his book almost unaided. We congratulate him on the result. . . . A volume which will take a worthy place amongst the accepted text-books of medicine."—THE LANCET.

By A. A. STEVENS, A.M., M.D., Professor of Applied Therapeutics in the University of Pennsylvania. Octavo of 1106 pages. Cloth, 35s. net.

W. B. SAUNDERS COMPANY, Ltd., 9, Henrietta Street, London, W.C.2.

A fine product from the celebrated laboratories of E. SCHERING—a guarantee of purity and reliability.

Samples and Literature on request from the Importers :

A. & M. ZIMMERMANN, LIMITED, 3, Lloyd's Avenue, London, E.C. 3

See Veramon announcement on inside back cover.

Valentine's Meat = Juice

For **Quieting** the Irritable Stomach,
 for **Aiding** the Digestion and for **Sus-
 taining** and **Strengthening**. Valentine's
Meat-Juice is **Extensively Employed**
 in the treatment of

Phthisis.

Dr. Gouel, Physician in Chief of the Villepinte Hospital for Consumption, Paris, France : "VALENTINE'S MEAT-JUICE succeeds well in cases of Anæmia and in the treatment of Tuberculosis in an advanced stage when the stomach is intolerant."

Dr. Pietro Borromeo, Physician and Surgeon of the Hospital of Rome, Italy : "I have tried VALENTINE'S MEAT-JUICE in the Tuberculosis Division of the Hospital of the Holy Spirit, and have proved the great advantages that it renders for the nutrition of the consumptive. Pleasant to the taste of the most fastidious of the sick, it does not irritate the stomach; but stimulates the peptogastric functions so as to improve notably the appetite, even in cases of continuous and high fever and extreme loss of strength."

For sale by European and American Chemists and Druggists.

**VALENTINE'S MEAT-JUICE COMPANY,
 RICHMOND, VIRGINIA, U.S.A.**

THE LANCET

MODERN TECHNIQUE IN TREATMENT

VOLUME I.

IN response to a very widely-expressed desire on the part of readers of THE LANCET, it has been decided to issue in permanent form the Articles which have been appearing weekly for the past two years under the general title of MODERN TECHNIQUE IN TREATMENT.

It will be seen from the List of Contents of Volume I. that a very wide range of subjects comes under treatment ; but all the Articles agree in being written from an entirely practical point of view, and it may therefore be said that every one will be found of interest and value to the general practitioner who wishes to keep abreast of modern ideas and methods.

The first volume will comprise about 350 demy octavo pages, and will be published at 10s. 6d. net. It is hoped to issue this volume in April next. To subscribers who order their copies in advance of publication the price will be 7s. 6d. net (postage 9d. extra), and an Order Form for this purpose is attached.

The Contents of Volume I. and the Advance Subscription Form are given on pages 7 and 8 respectively.

MODERN TECHNIQUE IN TREATMENT *(contd. from opposite page)*

CONTENTS OF VOLUME I.

THE MEDICAL TREATMENT OF GALL-BLADDER DISEASE. By Sir Humphrey Rolleston, K.C.B., M.D., F.R.C.P.
 THE TREATMENT OF EARLY PULMONARY TUBERCULOSIS IN THE YOUNG ADULT. By Claude Lillingston, M.D.
 THE TREATMENT OF NEURALGIAS OF THE HEAD AND NECK. By Wilfred Harris, M.D., F.R.C.P.
 THE TREATMENT OF WHOOPING-COUGH. By T Izod Bennett, M.D., M.R.C.P.
 THE TREATMENT OF SCABIES AND PEDICULOSIS. By H. W. Barber, M.B., F.R.C.P.
 THE TREATMENT OF ABDOMINAL INJURIES. By Prof. Charles A Morton, F.R.C.S.
 THE TREATMENT OF AURAL DISCHARGE IN CHILDREN. By Harold Barwell, M.B., F.R.C.S.
 THE TREATMENT OF VAGINAL DISCHARGE. By Aleck W. Bourne, M.B. F.R.C.S.
 THE TREATMENT OF MINOR INJURIES TO THE EYE. By Sir John H. Parsons, C.B.E., F.R.C.S., D.Sc., F.R.S.
 THE TREATMENT OF EPILEPSY. By Gordon Holmes, C.M.G., C.B.E., M.D., F.R.C.P.
 THE TREATMENT OF INGUINAL HERNIA IN CHILDHOOD. By C. W. G. Bryan, M.C., F.R.C.S.
 THE TREATMENT OF OBLIQUE INGUINAL HERNIA IN ADULTS. By Prof. A. W. Sheen, C.B.E., M.S., F.R.C.S.
 THE TREATMENT OF ECLAMPSIA. By Gibbon FitzGibbon, M.D., F.R.C.P.
 THE TREATMENT OF CLUB-FOOT IN THE NEWLY-BORN. By Sir Robert Jones, K.B.E., C.B., F.R.C.S.
 THE TREATMENT OF INTESTINAL WORMS. By Robert Hutchison, M.D.
 THE TREATMENT OF PRIMARY OR SPASMODIC DYSMENORRHOEA. By Sir George Blacker, M.D., F.R.C.P., F.R.C.S.
 THE TREATMENT OF MEASLES. By F Foord Caiger, M.D., F.R.C.P.
 HEART FAILURE: PREVENTIVE TREATMENT. By John Parkinson, M.D., F.R.C.P.
 HEART FAILURE: THERAPEUTICS. By John Parkinson, M.D., F.R.C.P.
 TREATMENT OF GONOCOCCAL EPIDIDYMITIS AND ITS BEARING ON STERILITY. By Kenneth M. Walker, F.R.C.S.
 THE TREATMENT OF ANTE-PARTUM HÆMORRHAGE. By T. Watts Eden, M.D., F.R.C.P.
 THE TREATMENT OF RINGWORM. By Arthur Whitfield, M.D., F.R.C.P.
 THE TREATMENT OF CYSTITIS. By James B. Macalpine, F.R.C.S.
 THE TREATMENT OF HÆMORRHOIDS. By R. M. Rowe, M.D., F.R.C.S.
 THE PROPHYLACTIC TREATMENT OF PUERPERAL SEPSIS. By Florence E. Barrett, C.B.E., M.D., M.S.
 THE TREATMENT OF CYCLIC VOMITING. By Prof. George F Still, M.D., F.R.C.P.
 THE TREATMENT OF ASTHMA. By E. P. Poulton, M.D., F.R.C.P.
 THE TREATMENT OF TRAUMATIC RUPTURE OF THE URETHRA. By G. Grey Turner, M.S., F.R.C.S.
 THE TREATMENT OF HABITUAL CONSTIPATION. By Arthur F Hurst, M.D., F.R.C.P.
 THE TREATMENT OF THE HYPERTROPHIED PROSTATE. By Prof. Charles A. Pannett, M.D., B.S., F.R.C.S.
 THE TREATMENT OF INFANTILE ECZEMA. By H. MacCormac, C.B.E., M.D., F.R.C.P.
 TREATMENT OF EXOPHTHALMIC GOITRE AND OTHER FORMS OF HYPERTHYROIDISM. By Prof. George R. Murray, M.D., F.R.C.P.
 TREATMENT OF SYPHILIS IN THE WOMAN OF CHILD-BEARING AGE. By Margaret Rorke, M.B., Ch.B.
 THE TREATMENT OF ANÆSTHETIC SICKNESS. By J. Blomfield, M.D.
 THE TREATMENT OF ENURESIS. By Hugh Thursfield, D.M., F.R.C.P.
 MENORRHAGIA IN YOUNG WOMEN WITHOUT GROSS LESION. By John S. Fairbairn, M.B., F.R.C.S.
 THE TREATMENT OF CHRONIC ARTHRITIS. By W. H. Wynn, M.D., M.Sc., F.R.C.P.

THE TREATMENT OF GLYCOSURIA IN PREGNANCY. By George Graham, M.D., F.R.C.P.
 THE TREATMENT OF FLAT-FOOT. By A. S. Blundell Bankart, M.Ch., F.R.C.S.
 THE MEDICAL TREATMENT OF EARLY OR SUSPECTED DUODENAL ULCER. By John A. Ryle, M.D., M.R.C.P.
 THE TREATMENT OF RETENTION OF URINE. By J. Swift Joly, F.R.C.S.
 THE TREATMENT OF THE NEUROTIC. By S. A. Kinnier Wilson, M.D., B.Sc., F.R.C.P.
 THE TREATMENT OF BLEPHARITIS AND STYES. By R. Affleck Greeves, M.B., F.R.C.S.
 THE TREATMENT OF INTERNAL DERANGEMENT OF THE KNEE-JOINT. By R. C. Elmslie, M.S., F.R.C.S.
 THE TREATMENT OF CÆLIAC DISEASE. By Reginald Miller, M.D., F.R.C.P.
 THE TREATMENT OF VARICOSE VEINS. By Philip Turner, M.S., F.R.C.S.
 THE TREATMENT OF COLLES'S FRACTURE. By Harry Platt, M.S., M.D., F.R.C.S.
 THE TREATMENT OF PYELITIS. By Sir John Thomson-Walker, F.R.C.S.
 THE TREATMENT OF PROLAPSE. By Beckwith Whitehouse, M.S., F.R.C.S.
 THE TREATMENT OF EPISTAXIS. By J. Gay French, M.S., F.R.C.S.
 THE TREATMENT OF CHRONIC COLITIS. By Adolphe Abrahams, M.D., M.R.C.P.
 THE PALLIATIVE TREATMENT OF TOOTHACHE. By A. T. Pitts, M.R.C.S., L.R.C.P., L.D.S.
 THE ACUTE MENTAL CASE: ACUTE CONFUSION OR DELIRIUM. By Henry Yellowlees, M.D., M.R.C.P.E., D.P.M.
 THE ACUTE MENTAL CASE: ACUTE DEPRESSION AND ACUTE EXCITEMENT. By Henry Yellowlees, M.D., M.R.C.P.E., D.P.M.
 THE TREATMENT OF ACUTE OBSTRUCTION DUE TO GROWTHS OF THE COLON. By Harold W. Wilson, M.S., F.R.C.S.
 SQUINT IN YOUNG CHILDREN. By T. Harrison Butler, M.D.
 THE TREATMENT OF ACUTE SEPTIC INFECTION: SEPTICÆMIA. By A. E. Gow, M.D., F.R.C.P.
 THE SURGICAL TREATMENT OF HÆMATEMESIS. By A. J. Walton, M.S., F.R.C.S.
 THE TREATMENT OF NEPHRITIS: GENERAL PRINCIPLES. By Prof. Hugh MacLean, M.D., D.Sc., M.R.C.P.
 THE TREATMENT OF NEPHRITIS: ACUTE AND CHRONIC FORMS. By Hugh MacLean, M.D., D.Sc., M.R.C.P.

KEEP YOUR FOOT OFF THAT PEDAL

Many motorists use the clutch pedal as a foot rest. This is a bad habit which imposes undue wear on the clutch and the withdrawal mechanism, and originates in the need for constant gear changing. Run on "BP," the British Petrol, and gear changing is reduced to a minimum, for "BP" enables engines to develop maximum power and climb hills on top that would ordinarily call for an intermediate gear. In traffic, too, "BP" permits of a performance on top that makes constant changing unnecessary.

The Latest Apparatus for ARTIFICIAL MOUNTAIN SUN TREATMENT

(Ultra-violet Radiation)

**NEW MODEL
ULTRA-VIOLET
RADIATION
APPARATUS.**

[By Dr. PERCY HALL,
Author of
"ULTRA-VIOLET
RAYS."

E.D. 116. DR. PERCY HALL'S MODEL

This apparatus, as will be seen in the illustration, is mounted on a vertical column and is accurately counterweighted by counterweight moving within the vertical tube. Cross movement is brought about by exceedingly easy running movement which permits of the apparatus being manipulated with the greatest ease. It is also free to rotate round the vertical column. The improved quick-action simple striking-gear for the arc is a feature of this apparatus. This apparatus is designed to burn one tungsten and one carbon electrode, or alternatively 2 tungsten electrodes. The lamp is enclosed in a spun aluminium hood and is supplied complete with reducing mask so that the apparatus can be used either for local application or general application. Price includes reducing mask fitted with quartz lens, also a marble rheostat. The price for the apparatus for Continuous Current is £35. Ditto apparatus, but complete with motor transformer for Alternating Current, £70.

Patentees and Manufacturers :-

MEDICAL SUPPLY ASSOCIATION, LTD.,

167/185, GRAY'S INN ROAD, LONDON, W.C.1.

The largest X-Ray and Electro-Medical Apparatus Showrooms in the United Kingdom.

ULTRA-VIOLET RADIATION has been found to possess extremely valuable therapeutic properties, and is now being employed very extensively for many conditions, some of which yield so readily that it may be considered as a specific treatment.

The Radiation is produced by—

An arc lamp which burns special tungsten electrodes.

The skin readily reacts to the illumination, which causes precisely the same tanning effect as is produced by sunlight—first a reddening of the skin, followed by the usual brown tint, and finally scaling. The treatment can be controlled with ease by adjusting the distance between patient and apparatus, also by time of exposure.

In cases of **ANÆMIA, NERVOUS DEBILITY**, and other conditions of **NERVOUS AFFECTION**, also with persons suffering from inanition and prostration (such as f.i. in convalescence) the salutary effects of Ultra-violet Radiation display themselves in such a way that the patients become more animated and cheerful, look better, and have a good appetite, and sleep soundly. Their pulse becomes more normal, their weight increases, and nervous excitement disappears. This use of the apparatus alone would make its possession especially valuable to every doctor. To this must be added the special therapeutic advantages in quite a number of complaints which are not so readily and favourably influenced by other methods of treatment, and in which, in fact, are some of the greatest successes of Artificial Mountain-Sun treatment. It proves a safe and rapid cure for **RICKETS** and infants' teething **CONVULSIONS**; gives excellent results in certain forms of **TUBERCULOSIS**; and acts as a specific remedy in **SCROFULA**.

By its aid **WOUNDS** are quickly healed, the radiation resulting in rapid drying and cleansing, exhaustion of the suppuration, alleviation of the pain, rapid granulation, and formation of soft, plant cicatrices. The treatment acts with safety in very numerous **DISEASES OF THE SKIN**, particularly loss of hair, and give very satisfactory results in **ERYSIPELAS** and **PSORIASIS**. It is a positive cure for **CHILBLAINS** and **BOILS**, and effects considerable improvement, if not complete recovery, in **RHEUMATISM, GOUT, NEURALGIA**, and every illness with a reduced or disturbed assimilation. In quite a number of **HEART DISEASES**, especially weakness of the heart muscles, moreover in chronic **DISEASES OF THE KIDNEYS**, the heart will be invigorated, and the most troublesome symptoms alleviated or removed.

**E.D. 27.
TUNGSTEN
ARC LAMP.**

For Ultra-violet Radiation. The stand on which the apparatus is mounted provides free movement and adjustment in all directions. With each apparatus we provide a rheostat to control the current from the main electrical supply, which is included in the price of the instrument. This apparatus can only be used on a direct current electrical supply. For those who have an alternating current supply a motor transformer to convert the alternating current into direct current would be necessary. Quotations on receipt of particulars of alternating current supply. **PRICE** complete with rheostat £24; ditto Apparatus, complete with motor transformer for alternating current £59. . . .

AWARDED THE CERTIFICATE OF THE INSTITUTE OF HYGIENE.

STERAID^{REGD}

SERIES OF

ABSORBENT AND MEDICATED GAUZE AND LINTS.

MADE IN ENGLAND.

An entirely new and original departure in the packing of Surgical Dressings.

This series is offered to provide a Surgical Dressing, which after packing retains its aseptic condition most nearly approaching perfection. The dressings after being placed in the Patent Containers are not handled or exposed to the atmosphere again.

In use, only the amount required is drawn out and cut off, the remainder of the contents is not exposed or handled, the whole operation being exceedingly simple and consisting of four motions only (*i.e.*, rotating outer cover to expose end of dressing, drawing out sufficient quantity, cutting off, rotating to close).

The "Steraid" series offers a great advantage over all other forms of Dressings, sufficient of the dressing for use is immediately available for application, and the remainder promptly re-sealed in the Patent Container, thus obviating the risk of exposure to dust and germs in the atmosphere, which occurs when the whole of the dressing has to be removed from a Carton or Package.

Medicated Gauzes should be preserved from the light, as being volatile they deteriorate. The "Steraid" series will be found eminently suitable for such dressings.

Supplies can be obtained from:—

Medical Supply Association, London.

TESTOGAN

For Men

Formula of late Dr. Iwan Bloch.

After twelve years' clinical experience
this product stands as a proven specific.

INDICATED IN

IMPOTENCE AND INSUFFICIENCY OF THE HORMONES.

Contains the hormones of the reproductive
glands and of the glands of internal secretion.

Special Indications for Testogan:

Sexual Infantilism and Eunuchoidism in
the male. Impotence and sexual weak-
ness. Climacterium virile. Neurasthenia,
hypochondria.

DIRECTIONS: A tablet three times daily after meals.
Also in ampoules for intragluteal injection.

Extensive literature and case reports on request to the
CAVENDISH CHEMICAL CORPORATION,

Empire House, 175, Piccadilly, LONDON, W.1.

BISMOSALVAN

Iodobismuthate of Quinine.

Guard against arsenic and mercury treatment
complications

* *

Least noxious specific for prolonged treatment of:—
Primal and Superimposed Infections in all
Stages;

Patients Resistant to Arsenic and Mercury
Preparations;

Hereditary Infection in Infants and Children;
Syphilis during Pregnancy;

Emaciated, Debilitated and Hypersensitive
Patients;

Neurosyphilitic Conditions.

NO GINGIVAL DISCOLORATIONS.

NO STOMATITIS.

NO KIDNEY DISTURBANCES.

Prophylactic in Post-Arsenical Supplementary
Treatment.

PHYTIN

(Calcium magnesium salt of inositol hexaphosphoric acid)

**A POWERFUL NERVE FOOD
AND GENERAL TONIC.**

An organic phosphorus combination of vegetable origin,
assimilable and non-toxic, containing 22% of phosphorus,
i.e., 6½ times more than lecithin.

"The most assimilable of all phosphorus combinations."
Manquat, "Treatise of Therapeutics," 1912, vol. II., page 267

"May be classified among the most powerful modifiers of nutrition."
Gilbert & Lippmann, "La Presse Médicale," 1904, No. 73.

Alkia Saltrates

This saline aperient presents certain features which we believe to be unique amongst preparations of its class.

THE ingredients of Alkia Saltrates are combined in such proportions as to produce an exceptionally well-balanced and synchronous action upon all of the various organs affected. For instance, this formula does not act as a violent purgative with little or no effect as an hepatic stimulant. On the contrary, whilst having a very thorough laxative action, it arouses the liver and promotes a free flow of bile, therefore being of special value in clearing congestion of the liver and preventing such obstructions as gall stones. Alkia Saltrates is also an efficient antacid and diuretic. As a moderately strong anti-rheumatic agent, it has met with unusual success.

All materials are the purest obtainable and specially tested before compounding, to make sure of the complete absence of any harmful impurities. Each constituent responds fully to the B.P. test and in certain particulars answers to higher tests.

In spite of the really heavy dose of alkaline and saline ingredients provided, Alkia Saltrates is neither lowering nor griping in its effects and it is very palatable. It is stocked by all chemists, the price being 3/3.

A full-size bottle, for practical test, will be sent postpaid on receipt of a request from any member of the medical profession.

ADVANCE IN TREATMENT
of
Hyperchlorhydria and Associated Conditions

TRADE MARK **ALOCOL** BRAND

Colloidal Hydroxide of Aluminium

Modern medical experience has proven that while the usual alkalis and oxides possess power for neutralizing the normal or abnormal acids of the stomach their action is only symptomatic and transitory. They may give momentary relief to the painful condition, but they also have the effect of aggravating the morbid condition. For this reason they are distinctly contra-indicated, especially in stubborn cases.

"Alocol" does not neutralize acid; it absorbs the excess colloido-chemically and at the same time leaves a sufficiency for normal gastric digestion. The outstanding advantage of "Alocol" as an antacid is that it removes from the system the causative acid radicle (Cl), instead of merely temporarily neutralizing it. "Alocol" can be used for prolonged periods without the slightest harmful effect.

A supply for clinical trial with full descriptive literature sent free on request.

M.198.

TABLETS

POWDER

"Alocol" is indicated in all conditions in which diagnosis reveals high gastric acidity. It is particularly valuable in the treatment of chronic affections of the stomach, the dyspepsias, especially those of pregnancy, gastric and duodenal ulcer, gastrosuccorhea and in conditions characterized by gastralgia, pyrosis, flatulence, acid eructation and other symptoms common to gastric disease.

INTESTINAL STASIS

The Advantages of Virolax The Nutrient Laxative

Perfect emulsification of the Paraffin so that its uncertain action is avoided.

The administration of an easily digested food with a bowel lubricant, without overloading the already distended intestine.

Complete lubrication of the bowel, directly facilitating the progress of the intestinal contents and inhibiting undue bacterial growth and the production of microbic toxins.

Virolax and Intestinal Bacteria

Investigations have shown that Virolax has a peculiar selective action on certain bacteria which are known to be the cause of intestinal toxæmia. This fact goes far to explain the results of the Clinical use of the preparation and demonstrates the superiority of Virolax over liquid paraffin in its pure state.

Trufood offers the only scientific equivalent for Human Milk

Humanised Trufood is made at the Creameries, Wrenbury, from the purest milk that comes from the rich pastures of the Cheshire dairy country. As the accompanying analysis shows, it is the closest approximation to human milk available for the physician who is called upon to advise an alternative to the breast, owing to deficiency or poverty of the natural supply. This result has been achieved by removing a part of the casein of full-cream Cheshire milk, so that after the addition of suitable quantities of pure cream and lactose, a humanised milk powder of the following composition results :

	Breast Milk	Cows' Milk	Humanised Trufood
	%	%	%
Lactose	6.5	4.7	6.25
Fat	3.3	3.5	3.45
Casein	0.9	3.0	0.80
Lactalbumin	0.4	0.3	0.60
Salts	0.2	0.8	0.65
Water	88.7	87.7	88.25
	<u>100.0</u>	<u>100.0</u>	<u>100.00</u>

We are exhibiting at the Nations Food Exhibition, April 11th to May 2nd, Stand No. 152, Main Hall, where scientific data of an interesting nature will be available to Doctors and Pharmacists.

**No other baby food on the market can
make this claim.**

You are invited to apply for reproduction of actual photograph (in colours) of a recent incubation test of various milks. This is obtainable by post.

T.F. 104-29

“MARSHALL’S”

THE list of Antiseptic substances is a fairly comprehensive one. The number of antiseptics capable of practical and easy application are few.

First and perhaps foremost of these is undoubtedly LYSOL—a saponaceous preparation of the three cresols—*ortho*-cresol, *meta*-cresol, and *para*-cresol.

These cresols vary in their bactericidal activity, and much depends upon the right selection when used in manufacturing.

The production of antiseptics and disinfectants that shall fulfil all requirements is the outcome of lengthy research and skilful manufacture—they cannot be prepared and standardised by small inexperienced makers.

For this reason, and owing to the number of substitutes offered to Surgeons and Doctors, it is necessary to specify “MARSHALL’S” when ordering or prescribing “Lysol” to ensure the genuine original product, which is guaranteed free from causticity and the impurities which give rise to irritation and frequently cause intense pain.

MARSHALL’S LYSOL does not attack the skin or numb the hands. Its use generally will be found quite agreeable.

**Marshall’s Lysol can be obtained in
all the Dominions and Dependencies.**

A four-ounce Bottle will be sent upon request by the Sole Makers—

Rapid Headway after Influenza

The present epidemic is providing the medical profession with further evidence of the power of 'Roboleine' to build up the system.

Roboleine

has always owed a great deal to the support of medical men, but at this time particularly we are experiencing the effects of its prescription to a degree unprecedented in the history of the firm.

In all cases where progress is slow, 'Roboleine' will prove of great benefit, for it provides a means of administering nourishment without overburdening the system.

REDUCTION IN THE PRICE OF

AETHER PURISS. B.D.H.

Absolute Ethyl Ether for the production of
Anaesthesia without Bronchial Irritation or Nausea.

THE BRITISH DRUG HOUSES, LTD., the manufacturers of AETHER PURISS. B.D.H. have pleasure in announcing that, as a result of the greatly increased scale of manufacture, they are enabled already to make a substantial reduction in the price of this product.

AETHER PURISS. B.D.H. is manufactured exclusively in the Chemical Works of The British Drug Houses, Ltd., under conditions which ensure very close scientific supervision and exacting analytical control.

A gratifying and ready reception has been accorded to this new ether by leading anaesthetists, whose prompt appreciation, following clinical tests, is based upon the following characteristics:—

1. It is the most stable form of ETHYL ETHER which can be obtained.
2. It gives no reaction to the exceedingly delicate ferrous thiocyanate test for organic peroxide, thus indicating the absence of this toxic impurity.
3. It contains no decomposition products which produce post-operative retching and nausea.
4. It is issued in amber bottles made specially for the purpose, wrapped in black paper; the action of light is thus entirely precluded.

A descriptive pamphlet and particulars of reduced prices will be sent on request.

Micro-photograph of stool after Petrolagar administration, showing complete emulsification and thorough admixture with intestinal content.
[1] Epithelial Cells [2] Microscopic Oil Globule [3] Agar-Agar Granule.
[4] Faeces

Micro-photograph of faeces after administration of plain mineral oil, showing complete absence of emulsification: this explains why mineral oil always leaks.
[1] Epithelial Cells [2] Oil Globule [3] Faeces

Petrolagar

(trade mark)

SUPERSEDING LIQUID PARAFFIN IN THE TREATMENT OF CHRONIC CONSTIPATION

THE micro-photographs clearly demonstrate the superiority of Petrolagar over ordinary liquid paraffin in the treatment of constipation. On the left the perfect admixture with the intestinal content obtained with Petrolagar is apparent: the other photograph, in which large unemulsified globules of oil are present, explains at a glance why plain mineral oil never has solved and never can solve the problem of constipation. It also shows why mineral oil leaks.

The drawbacks inseparable from the use of plain liquid medicinal paraffin are well known. Many patients cannot tolerate its insipidity; digestive disturbances sometimes occur; whilst thorough admixture with the intestinal content is seldom attained, with consequent leakage from the rectum. These difficulties are overcome in Petrolagar, which contains 65% of pure medicinal liquid paraffin with 10% of prepared agar-agar, in the form of a highly stable and extremely palatable emulsion. There is no taste of oil, so that the most fastidious patients take the product readily. In the treatment of chronic constipation, Petrolagar gives results unobtainable by any other method and breaks the vicious circle set up by the habitual use of drastic purgatives. The medicinal paraffin is so finely divided that it is thoroughly disseminated throughout the faecal mass and *cannot leak*; the agar-agar is specially prepared so as to yield on incubation in the intestinal tract many times its original bulk, forming a bland gelatinous mass which is completely and readily eliminated, acting, indeed, as a soothing emollient to the inflamed intestinal mucosa. As contrasted with cathartics, Petrolagar is non-habit forming, and once normal elimination has been restored may be given in diminishing quantity.

PETROLAGAR is available in four forms: PETROLAGAR Plain PETROLAGAR Alkaline
PETROLAGAR Phenolphthalein PETROLAGAR Unsweetened.

LIQUOR SEDANS

Utero-Ovarian Sedative

EACH FLUID OUNCE REPRESENTS:

Viburnum Prunifolium ...	60 grains
Hydrastine to represent Fl. Ext. Hydrastis ...	30 minims
Piscidia Piscipula ...	30 grains
Aromatics ...	q.s.

LIQUOR SEDANS (P., D. & Co.) was introduced to the medical profession in the year 1888, and notwithstanding the many additions to materia medica that have been made since that date, it still holds a foremost place as a proved remedy for pelvic congestions and inflammations requiring tonic-sedative and antispasmodic treatment.

LIQUOR SEDANS is of special value in the treatment of menorrhagia, metrorrhagia, dysmenorrhœa, endometritis, perimetritis and ovaritis; it is also prescribed in the treatment of subinvolution and in cases of impending abortion.

The dose of Liquor Sedans is from 1/2 to 1 teaspoonful in hot water, three or four times a day; in cases attended with severe pain it may be given every one or two hours.

LIQUOR SEDANS (P., D. & Co.) is supplied in bottles of 4, 8, 16 and 80 fluid ounces.

LIQUOR SEDANS GLOBULES (gelatin capsules containing the equivalent of 1 teaspoonful of the Liquor) are supplied in boxes of 12, 25 and 100.

In the Insulin Treatment of Diabetes the diet is still a factor of vital importance.

Allenburys' Diabetic Flour

Is a special preparation of caseins and lactalbumen to which leavening agents are added.

It is a satisfactory and convenient product for the preparation of special foods, free from carbohydrates, and containing a minimum of fat; or definite proportions of these may be added as tolerance increases with the progress of the treatment. The 'Allenburys' Diabetic Flour is compact, convenient to use, and keeps well. From it may be prepared a variety of palatable and highly nutritious foods of special composition. Recipes and directions for use are enclosed with each packet.

COMPOSITION:

	Per cent.
TOTAL PROTEINS	87.0
FAT	0.7
SODIUM BICARBONATE	1.6
ACID POTASSIUM TARTRATE	1.6
MOISTURE	9.1

Calorific Value—303 calories per 100 grammes
or 1,376 calories per lb.

A Doctor writes:

"I have tested the sample of 'Allenburys' Diabetic Flour which you recently sent me and find it makes admirable bread, etc.; it is both more easily digested and more palatable than any similar preparation I have come across."

Further particulars and clinical trial sample
will be sent on request.

How do you reduce Temperature in Broncho-Pneumonia?

HOLT says—"It must be remembered that the normal range of temperature in Broncho-Pneumonia is from 101° to 104.5° F. This temperature is not in itself exhausting, and the chances of recovery are not, I think, improved by systematic efforts at reducing it so long as it remains within these limits.

"Too much cannot be said in condemnation of the practice of giving drugs for reduction of temperature."

Antiphlogistine hastens the elimination of toxins

thus favoring a decline in temperature.

Applied hot and thick over the entire thorax, Antiphlogistine, in a mild, yet effective manner, bleeds the patient into his own superficial capillaries; the pain lessened, temperature declines, deep-seated congestion and dyspnoea are relieved, while the heart, having a smaller volume of blood to deal with, conserves its strength.

Over 100,000 Physicians have used the genuine Antiphlogistine for 30 years. It is a scientific, not empirical, preparation.

Let us send you our booklet "The Pneumonic Lung"—it is replete with very valuable information and is FREE.

The Denver Chemical Mfg. Co.,

London, E. 3.

Antiphlogistine
TRADE MARK
"Promotes Osmosis"

Diagram represents inflamed area. In zone "C" blood is flowing freely through underlying vessels. This forms a current away from the Antiphlogistine, whose liquid contents, therefore, follow the line of least resistance and enter the circulation through the physical process of endosmosis. In zone "A" there is stasis, no current tending to overcome Antiphlogistine's hygroscopic property. The line of least resistance for the liquid exudate is therefore, in the direction of the Antiphlogistine. In obedience to the same law exosmosis is going on in this zone, and the excess of moisture is thus accounted for.

Antiphlogistine poultice after application. Center moist. Periphery virtually dry.

In Pulmonary Diseases

Horlick's Malted Milk, by supplying nourishment in an easily-digested form especially adapted to enfeebled digestive powers in conditions associated with metabolic unbalance—in which there is the ascendancy of the products of destruction over those of reconstruction—presents the best form in which milk can be given, and is one of the most important factors, as an enriched diet, in the prophylactic and active treatment of all Pulmonary and allied affections. Complete in itself and ready in a moment by briskly stirring the powder in hot or cold water only.

Liberal samples free to Members of the Profession.

ASKLEPIOS, THE PIONEER OF GREEK MEDICINE.—It is from Homer that we gain our first knowledge of Greek medicine. He refers to physicians who ministered to the wounded in the Trojan War and to Asklepios, not as the "God of Medicine," which he became later, but as a real person, a Thessalian chieftain and hero divinely skilled in medicine. His sons, Machaon and Podaleirios, to whom he had taught his art, accompanied the Greek host against Troy as physicians and surgeons. In the Iliad there is no hint of healing by a god; natural means alone are described, though in the later Odyssey there are references to charms. The pioneer Greek physicians were acquainted with the science and art of cleansing and binding wounds and of healing them by the application of anodyne drugs and dressings. They prepared reviving drinks; they were aware of the after-effects of certain injuries. They allayed pain by the application of powders and poultices often made from roots. A Homeric tonic was composed of Prammiam wine, onions, honey, grated goat's milk cheese, and flour. They had a rough knowledge of anatomy, acquired chiefly upon the battle-field. They referred the life-spirit, or breath, to the diaphragm; this, while not exact science, led to the knowledge that a wound in this region was fatal. Asklepios was the pioneer in Homeric medicine. In later generations he was looked upon as a god; temples were built in his honour, and to them flocked the sick for treatment.

Date: c. 1000 B.C. or c. 900 B.C.

COPYRIGHT

THIS PREPARATION IS NOW OBTAINABLE IN 5-oz. BOTTLES.

MIST. HEPATICA CONC. (HEWLETT'S)

COMPOSITION.—Ext. Cascara, Ext. Rhei, Jalapin, Podophyllin, Cocainæ Hydrochlor., 1-20th gr. in each fluid drachm.

This preparation does not come under the Dangerous Drugs Act.

THIS excellent compound, first introduced as a general aperient and cholagogue, has now become a popular remedy in that class of cases spoken of as Chronic Biliousness, in Catarrhal Jaundice, and in the Jaundice of simple Hepatic Torpor. In passive or habitual Congestion of the Liver, so frequently met with, it has been used with marked benefit.

In the treatment of acute or temporary constipation, frequently met with in the convalescence from acute disease and in pregnancy, or in the constipation due to sedentary habits, to a deficiency of intestinal secretion and of peristalsis, the mixture can be prescribed with wonderful effect.

The Dose is from 10 to 60 minims, according to the age and condition of the patient. One drachm is a direct aperient and is not accompanied by griping or tenesmus.

Packed for Dispensing only in 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. Bottles.

Price in England, 12/6 per lb.

Please write: "Mist. Hepatica Conc. (HEWLETT'S)" to ensure obtaining this Preparation.

This preparation is also supplied "sine Cocaina," the dose and price remaining the same.

*To Medical Men***GRANOSE BISCUITS.**

This is a cereal food in the form of flakes. The analysis gave the following figures:—

Water	3.02
Proteids	14.02
Soluble carbohydrates (chiefly dextrin)	32.98
Other digestible carbohydrates	44.52
Fat	1.73
Fibre	1.82
Mineral matter (chiefly phosphates)	1.91
	<u>100.00</u>

It has special value to those who have weak digestions or who suffer from dyspepsia, and to athletes, hard workers, children, and all who undergo mental strain.

From our tests we are able to certify "Granose" to be a pre-cooked food of the highest possible dietetic value and scientific skill in manufacture.

Granose Biscuits are composed of "Granose Flakes" pressed in the form of oblong cakes, and have the same general composition, and valuable dietetic properties as the "Granose Flakes" detailed above.

(Signed) J. GRANT-STEPHEN, D.Sc., Ph.D.,
Director of Laboratories.

The subjoined analysis justifies our advocacy of GRANOSE BISCUITS for all cases of stomach trouble and weak digestion. Excellent for Infants—a boon to Invalids.

DR. DE JONGH'S LIGHT BROWN COD-LIVER OIL

In prescribing Cod-Liver Oil the Medical Profession can confidently rely upon Dr. de JONGH'S OIL giving the most uniform and satisfactory results. Dr. de Jongh's Light Brown Cod-Liver Oil is prepared from the oils obtained from the livers of fish caught in the region of the Loffoden Isles off the Norwegian coasts. The oils are naturally produced, and no process in their preparation or mixing can conduce to the destruction, either partial or total, of the vitamins which are now recognised as being such an important factor in dietary and a valuable adjunct to medical treatment. The proprietors, Ansar, Harford & Co., Ltd., 182, Gray's Inn Road, London, have always maintained the high quality which the late Dr. de Jongh insisted was essential if the full curative value was to be obtained. It will be found invaluable in the treatment of Diseases of the Throat and Chest, Infantile and all Wasting Diseases.

Sold in Imperial Pints and Half-Pints by all Chemists.

HAIR GROWTH BY NUTRITION.

*A Scientific Preparation for preserving the Hair,
preventing its loss and promoting new growth*

This remedy introduces a new feature into the treatment of hair troubles, such as loss of hair and partial or complete baldness due to malnutrition. It is given internally in the form of tablets. Its action is that of a specific nutrient stimulant to the growth of epidermal structures. Its claim may be gathered from the following quotations from leading medical journals.

"The Lancet," December 18th, 1920.

"Hair restoration by the use of special foodstuffs."
"N. Zuntz, the distinguished chemical physiologist of Berlin, takes a . . . philosophic view as to the conditions likely to influence the growth of hair or wool. He recalls the fact that in the early decades of the nineteenth century the question was raised as to whether the woolly coat of sheep could be improved by the nature of the diet. Proceeding on the supposition that given an increased supply to the hair papillae of the proximate organic material out of which is manufactured keratin—the organic basis of certain epidermic appendages—it might be possible to influence favourably the growth of wool and hair."

"In man—Zuntz himself—before the experiment the daily growth of new hair was calculated as 5 mg. With the daily addition of 1.15 g. of the hydrolised products to the dietary in the first four weeks the amount was 6.3 and in the subsequent four 9.12 mg. Even after the withdrawal of the keratin products the increase in the growth of the hair continued for several months."

Dr. H. B., writes:—

"I used Humagsolan in the case of a female patient who had lost a great deal of hair during her confinement and in the subsequent nursing period. I was astonished to see how quickly a new growth of hair began."

"Medical Press and Circular," March 7th, 1923.

The remedy has been introduced in a scientific form and with excellent credentials. It is therefore worthy of extended trial.

FREE We shall be pleased to send to any member of the medical profession a full month's supply of Humagsolan with covering literature for practical testing purposes **FREE**.

PRICE 12/6 for one complete month's Treatment.

Faraday House, 10, Charing Cross Road, LONDON, W.C.2

Antikamnia Tablets

**Strongly Recommended in:
INFLUENZA & LA GRIPPE**

For the headache, pain, and general soreness give a five-grain Antikamnia Tablet crushed with a little water; if the pain is very severe two tablets should be given. Repeat every 2 or 3 hours as required. One single ten-grain dose is often followed by complete relief.

NEURALGIA

In the Treatment of Neuralgia and Myalgic Pains Antikamnia Tablets are not only palliative, but, along with other measures, assist in ultimate cures; they also have a field of use in Rheumatic and Gouty Affections. In Neurasthenia, Hysteria, and Migraine they are a valuable adjuvant to the other recognised therapeutic measures.

LARYNGEAL COUGH

Frequently remains after an attack of Influenza, and has been found stubborn to yield to treatment. There is an irritation of the larynx, huskiness, and a dry and wheezing cough, usually worse at night. The prolonged and intense paroxysms of coughing are controlled by ANTİKAMNIA & CODEINE TABLETS, and with the cessation of the coughing the laryngeal irritation subsides.

Antikamnia Tablets are the least depressing of all the drugs that can exercise so extensive a control of pain, and also least disturbing to the digestive and other organic functions.

A SAMPLE

of generous size will be sent all medical men sending their professional card. Also interesting literature.

Analgesic. Antipyretic. Anodyne.

Antikamnia Preparations in 1-oz. packages only.

JOHN MORGAN RICHARDS & SONS Ltd.,

HALITOSIS

(AS DEFINED IN THE CENTURY DICTIONARY)

(Hal-i-to-sis) N. N. L.

(L. Halitus—Breath :: :: Osis—Offensive)

Offensive breath, whether arising from diseased or neglected conditions of the teeth, mouth or nose or caused by disorders of digestion, respiration, the excessive use of tobacco, etc., may be readily overcome by the deodorizing properties of—

LISTERINE

Listerine is strictly antizymotic, it inhibits alike the acid fermentation of carbohydrates and the alkaline putrefactive processes of mixtures of meat and saliva, retained as debris about the teeth; hence, Listerine is antagonistic to the activating enzymes of fermentation so often the cause of Halitosis.

The volatile antiseptic constituents of Listerine—thyme, eucalyptus, gaultheria and mentha, combined with baptisia, boric acid, rectified spirits and water have a stimulating effect upon the stomach and in proportion to the dose, an action inhibitive to fermentation of its contents; hence, Listerine is often corrective of those disorders associated with the endo-development of gases and acid eructations. A large tablespoon of Listerine in a wine glass of hot water will afford immediate relief.

LAMBERT PHARMACAL COMPANY <Twenty-first and Locust Streets,>
St. Louis, Mo., U.S.A.

THE HEALTH OF THE NATION

is of paramount importance and in a large measure depends on robust and healthy children.

NESTLÉ'S MILK

THE RICHEST IN CREAM

whether used as a complete diet for infants or as a supplementary food, has achieved remarkable results during three Generations.

While it contains all the life-giving vitamins of fresh milk, as indicated by exhaustive experiments made at the Lister Institute, Nestlé's Milk is absolutely clean and pure as well.

On tabulating reports of lengthy investigations concerning children reared on Nestlé's Milk, we arrive at these eloquent figures:—

For every 100 infants at the average age of 2½ years reported on:—

Deaths from disease	-	1.86%	Unwell at time of reporting	0.77%
Deaths from accidents	-	0.14%	In perfect Health	- 97.23%

NESTLÉ'S, 6 & 8, EASTCHEAP, LONDON, E.C.3.

THE FRENCH NATURAL MINERAL WATER

VICHY-CÉLESTINS

And the other State Springs of Vichy
(Property of the FRENCH STATE.)

**FERMENTATIVE DYSPEPSIA.**

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation. **Vichy-Célestins**, by its slightly stimulating action, clears out the stomach, and this avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ÉTAT" and the name of the SOLE AGENTS:—

INGRAM & ROYLE, Limited,

Bangor Wharf, 45, Belvedere Road = = = London, S.E. 1.

Influenza Prophylaxis.

PINEOLEUM BRAND INHALANT is a Chemically and Bacteriologically standardised preparation for the medication of the Mucous Membranes of the nose and throat.

It possesses a high index of inhibition against the organisms usually present in chronic and epidemic nasal catarrh and is particularly selective to Pfeiffer's Influenza Bacillus.

It will be found to be an ideal preparation for prophylaxis and treatment of Influenzal conditions.

FREE SUPPLIES of Pineoleum Brand Inhalant (including nebulizer) with Clinical Research Laboratory Certificate of Inhibition indices will be supplied to Physicians on application to:—

A.D.S. Co. (British Agents),
40-42, Lexington St., LONDON, W.I.

PRESCRIPTION (Humanised) GLAXO

Prescription Glaxo is a product which combines the advantages of a dried milk produced under the best possible conditions with those of milk so modified that it has the same low protein and high carbohydrate value as breast milk as the following analyses show:—

DRIED		LIQUID	
FAT	24.8	FAT	3.1
PROTEIN	13.6	PROTEIN	1.7
CARBOHYDRATE	55.2	CARBOHYDRATE	6.9
ASH	3.7	MINERAL MATTER	0.5
NATURAL CITRATES	0.4	WATER	87.8
MOISTURE	2.3		

The carbohydrate contained in Prescription Glaxo is Lactose only.

Reconstituted with hot boiled water, 1 in 8 (1 part of powder made up to 8 parts with boiled water, allowed to cool to about 160 F.

Prescription (Humanised) Glaxo is therefore practically identical in composition with average breast milk.

GLAX-OVO

"EVERY DROP SHEER NOURISHMENT"

In the short time that it has been on the market, this new food-drink has met with an increasingly favourable reception from the Medical and Nursing Professions.

Glax-ovo contains milk, malt extract, and cocoa, together with the "Vitamin Concentrate" which is extracted from its richest known source, cod-liver oil. Glax-ovo "provides a means of obtaining the benefit of cod-liver oil without its unpleasant qualities of flavour and repetition."—*The Lancet*, Sept. 27, 1924

Note.—This "Vitamin Concentrate," which is incorporated in Glax-ovo alone, is now sold under the registered name of "OSTELIN." In this form the actual substance is diluted with glycerine so that three drops of the glycerine suspension are equivalent to one teaspoonful of cod-liver oil.

Prepared by the Glaxo Laboratories,
London, N.W.1. Samples and special literature concerning these products will gladly be sent on receipt of name and address

PULMO (BAILLY)

A Marked Advance in Scientific Pharmacy

*Ensures the remineralisation of the Organism
and the Encapsulation of Bacillary Lesions*

PULMO, unlike the old-fashioned pharmaceutical preparations of phosphates and calcium, which were not assimilated, but passed through the body unchanged, contains these mineral substances in the ionized state (introduced by Prof. Stephane Leduc and Dr. A. Bouchet). Consequently they are eminently active, and ready to form stable combinations with the constituent elements of the organism.

PULMO is indicated in Influenza, Catarrh, Colds, Laryngitis, Tracheitis, Bronchitis, Asthma, Pneumonia, and all Pre-Tubercular states.

PULMO has a world-wide reputation among Medical men, as a most efficient combination of those principles which act specifically on the diseased tissues and morbid secretions of the Respiratory Tract.

Until a very short time ago, the bottle-fed baby and his mother were at a distinct disadvantage. Feeding time was attended with various discomforts, then thought inseparable from the bottle method.

The new Cow & Gate Feeder—simple, efficient and hygienic—is the outcome of careful study of Baby's sucking power; no leakage, no hand-tiring, no guess-work.

There are numerous new and important features in the Cow & Gate Feeder. The flow of food can be nicely regulated by the zig-zag groove in the octagonal glass-stopper (secured by a moveable rustless clip so that Baby cannot remove it.) Clearly marked for ounces and table-spoons. Patent pure rubber teat, internally ribbed so that it has only to be rolled between the fingers to be cleared of any secreted food, but cannot be slipped off by Baby. Bottle has a flat base, and can be stood without food reaching the teat.

Stopper, clip and teat can be removed by Mother in three seconds, and the bottle flushed from end to end. The whole Feeder is well-balanced, easily held, and cannot get out of order in any way. It realises the dream of thousands of Mothers and Nurses.

ANGLIN & Co. 68, Milton Street, London, E.C.

ORAL SEPSIS.

**"EUMENTHOL
JUJUBES"**

(HUDSON)

Made in Australia.

A Gum pastille containing the active constituents of well-known Antiseptics, Eucalyptus Polybractea (a well-rectified Oil free from aldehydes (especially valeric aldehyde), which make themselves unpleasantly noticeable in crude oils by their tendency to produce coughing), Thymus Vulg., Pinus Sylvestris, Mentha Arv., with Benzo-borate of Sodium, &c., they exhibit the antiseptic properties in a fragrant and efficient form. Non-coagulant antiseptic and prophylactic, reducing sensibility of mucous membrane.

THE LANCET says:—

"In the experiments tried the Jujube proved to be as effective bactericidally as is Creosote."

Mr. W. A. DIXON, F.I.C., F.C.S.,

Public Analyst of Sydney, after making exhaustive tests, says:—

"There is no doubt but that 'Eumenthol' Jujubes have a wonderful effect in the destruction of bacteria and preventing their growth.... I have made a comparative test of 'Eumenthol' Jujubes and Creosote, and find that there is little difference in their bactericidal action."

THE PRACTITIONER says:—

"They are recommended for use in cases of oral sepsis, a condition to which much attention has been called in recent years as a source of gastric troubles and general constitutional disturbance, and are also useful in tonsillitis, pharyngitis, &c."

THE AUSTRALASIAN MEDICAL GAZETTE states:—

"Should prove of great service."

Manufacturers of Pure Eucalyptol (Cineol).

SULFARSENOL.**THE ARSENOBENZENE OF CHOICE IN THE TREATMENT OF SYPHILIS.**

(In use in the Civil and Military Hospitals in France.) Of all forms of Arsenobenzene **SULFARSENOL** is:

THE LEAST DANGEROUS because it is free from arsenoxide; because it is from 2 to 5 times less toxic than the other Arsenobenzenes, because, being freely soluble, it may be injected intravenously, intramuscularly, or subcutaneously with equal satisfaction and without a special menstruum.

THE MOST EFFICACIOUS because the variety of its modes of administration permits of its application to the exigencies of each particular case, and renders possible the intensive treatment by cumulative doses which secures a therapeutic effect as rapid as it is thorough and permanent.

N.B.—**SULFARSENOL** has a specific action on the acute complications of Gonorrhoea; relief follows the first injection (18-24 centigr.), and subsidence without relapse in a few days.

**EVERY DOCTOR
WILL APPRECIATE**

the hygienic excellence of a Sindix Hairbrush. Any Doctor, who sees and tries one, will both use it and recommend it. Many have done so already, and it is being used in a large number of clinics. If you have not already tried a Sindix, we will gladly send you one for a 3 days' test. Then send 12/6 for either handled or military shape, if you are satisfied. Otherwise, return the brush and there is no charge or obligation.

The back is of polished aluminium, perforated to allow instant, thorough cleansing. The "bristles" are fine, glistening chromaloy wire, which penetrate the hair and stimulate its growth, but do not irritate the scalp. The whole brush can be boiled, soaked in disinfectants, or passed over the flame of a spirit lamp without injury. Awarded a Certificate by the Institute of Hygiene, it is "the clinic brush."

RAZOR BLADES.—If you use a Gillette type razor write to us for a free trial Sindix blade. They are made by a new process, hollow ground, 2/6 doz.

*Why not send Patients suffering
from Foot Trouble to*

CHARLES H. BABER.

The majority of cases only require the ARCH PRESERVER SHOE, fitted by my "Heel-to-Ball" method, in order to get relief.

My Shoe Fitting Service includes the examination of the feet by X-ray without extra charge. This, combined with my "Heel-to-Ball" method of fitting, and the supplying of "ARCH PRESERVER SHOES" where necessary, ensures an absolutely perfect fit and correct support for the arch of the foot.

I have given relief to thousands who have suffered from foot troubles. If you can spare the time to call I shall be pleased to demonstrate my method and show you how completely my Shoe Fitting Service surpasses all others.

Charles H. Baber.

NOTE! Upper Regent Street is being repaved during March and April. Your chauffeur can use Margaret Street, where we have a side entrance in Langham House.

The Doctors' Portable Remington

possesses all the recognised advantages of this wonderful portable machine, plus a keyboard containing the special symbols used by the profession. It has the big machine four-bank keyboard arrangement, 42 keys writing 84 characters. No shifting for figures.

A Helpful Time-saver

The busy doctor will find the light, handy, serviceable Remington indispensable to his practice and a great time saver. It turns out work of the highest legibility and accuracy at astonishing speed. A special Drug Label Attachment enables neatly typed labels to be produced as required.

The Remington Portable is the most complete of all portable typewriters—with four-bank keyboard, automatic ribbon reverse and every feature common to the big machines. Yet it fits in a case only four inches high. So handy it can be used anywhere, and so small it can be tucked away in a corner when not in use.

And all other Surgical Degrees and Diplomas.

- † The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.
- † Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Exams. on several previous occasions get through without difficulty after going through our courses.
- † The Surgical Tutors of the College all hold either the M.S. Lond. or F.R.C.S. England, or both, and are highly experienced teachers.
- † The Postal Courses are thoroughly clear, concise, and up-to-date, and the test questions are carefully selected from those set at previous Examinations so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time and much unnecessary reading is saved.

March 11th, 1925.

FREDK. W. DREWETT, Director.

MINISTRY OF HEALTH

APPOINTMENT OF MEDICAL OFFICERS.

The Minister of Health invites applications from registered Medical Practitioners for appointment to act as Medical Officers of the Ministry in various parts of England and Wales, for the discharge of combined clinical and administrative duties in connexion with the National Health Insurance Medical Service and otherwise. Twelve Officers will be appointed for England and one for Wales, and their official designation will be Deputy Regional Medical Officer.

DUTIES.

The Medical Officers will be required to perform such duties as may be assigned to them by the Minister from time to time, and these will include acting as deputy to the Regional Medical Officer in the work carried out by the latter:—

- (a) As Medical Referee in cases of insured persons referred for a second medical opinion on questions of incapacity for work, or of restoration of working capacity;
- (b) In assisting in the administration of the Insurance Medical Service.

RESIDENCE.

Medical Officers will be required to reside in the area from time to time assigned to them.

REMUNERATION.

The rate of remuneration will be £800 per annum, rising by annual increments of £30 to a maximum of £1100. No cost of living bonus will be payable in addition thereto. Officers appointed to this scale will be established Civil Servants with the usual pension rights.

Successful candidates who are considered to possess exceptional or special qualifications may be allowed to enter the above scale at a commencing salary of £850 per annum. Above the grade of Deputy

Regional Medical Officer, there are at present 33 posts of Regional Medical Officers (30 in England and 3 in Wales) rising to a maximum of £1400 a year inclusive, and four posts of Divisional Medical Officers rising to a maximum of £1600 a year inclusive. The above numbers are, however, subject to revision from time to time as the exigencies of the Service may determine. When vacancies are to be filled among the Regional Medical Officers, preference will be given to those who have given satisfaction as Deputy Regional Medical Officers.

Applicants must be medical men of not less than 10 years standing and not exceeding the age of 50 years. Preference will be given to those having wide experience of general practice, especially amongst the industrial population. Further particulars of these appointments and forms of application may be obtained from the SECRETARY, MINISTRY OF HEALTH, WHITEHALL, LONDON, S.W.1.

Or for Wales:—

The SECRETARY, WELSH BOARD OF HEALTH, CITY HALL, CARDIFF. Letters applying for forms of application should have the words "Medical Officer" boldly written in the bottom left-hand corner of the envelope. No applications can be considered if received after the 15th April, 1925.

The Royal Dental Hospital of London,

Leicester-square, W.C. 2.

HONORARY ASSISTANT DENTAL SURGEON.

There is a second vacancy on the staff of this Hospital for an Honorary Assistant Dental Surgeon.

Candidates for the same, who must be Licentiates of Dental Surgery of one of the licensing bodies recognised by the General Medical Council of the United Kingdom, are requested to send in their applications, accompanied by testimonials and a list of appointments held, to the undersigned, from whom further particulars may be obtained, on or before March 30th, 1925.

W. J. WADHAM, Secretary.

Royal Chest Hospital, City-road, E.C.1

(Royal Northern Group of Hospitals.)

A vacancy occurs for a PHYSICIAN with charge of Out-patients. Candidates must possess the degree of M.D. or M.B. obtained by examination at a British University, and be Fellows or Members of the Royal College of Physicians of London.

Applications should be sent not later than 13th April to the undersigned, from whom particulars with regard to the appointment, attendances, and submission of testimonials may be obtained.

GILBERT G. PANTER, Secretary.

Royal Northern Hospital, Holloway, N.7.

The Hospital for Sick Children,

Great Ormond-street, London, W.C. 1.

A HOUSE SURGEON is required on 12th April, 1925.

A HOUSE PHYSICIAN and ASSISTANT CASUALTY OFFICER is required on 14th April, 1925.

Gentlemen are invited to send in their applications, addressed to the Secretary, before 12 o'clock, on Monday, 30th March, 1925, with copies of not more than three testimonials given specially for the purpose, and also evidence of their having held a responsible Hospital appointment.

The appointments are made for six months. Salary £50, laundry allowance £5, and board and residence in the Hospital. Candidates must be unmarried and possess a legal qualification to practise.

All candidates must be in attendance to appear before the Joint Committee if required at their meeting on Wednesday, 1st April, 1925, at 5 P.M. precisely.

Forms of application and copies of the rules may be obtained from the Secretary.

By order of the Board of Management.

March, 1925.

JAMES MCKAY, Secretary.

60

British Hospital for Mental Disorders

AND NERVOUS DISEASES, 72, Camden-road, N.W. 1. There is a vacancy for an HON. PHYSICIAN. Application to be made to D. IRVING, Secretary.

Candidates must be Graduates in Medicine of a University of the United Kingdom, and (a) Fellows or Members of the Royal College of Physicians in London, or (b) Fellows of the Royal College of Surgeons of England. Applications to be sent to the Secretary at the Hospital not later than April 11th, accompanied by a certificate of age and six copies of testimonials. For further particulars apply to ARTHUR WATTS, Secretary. 18th March, 1925.

Parish of Hammersmith.

DISTRICT MEDICAL OFFICER AND PUBLIC VACCINATOR.

The Guardians invite applications for the appointment of District Medical Officer for the No. 1 District, which is bounded on the south by the River Thames; on the west by Stamford Brook-road, on the north by Goldhawk-road, and on the east by Brackenbury and Iffley-roads and The Grove.

Salary £150 per annum (no bonus), subject to the provisions of the Poor-law Officers' Superannuation Act, 1896, in addition to the authorised extra medical fees allowed for midwifery and other cases.

The Guardians will also be prepared to enter into a contract with the successful candidate for the performance of public vaccination for the same District with remuneration according to the minimum rate named in the Vaccination Order (estimated fees £70 per annum).

Candidates must be duly registered in accordance with the Medical Act of 1838, and possess certificates of efficiency in Vaccination, and the gentleman appointed will be required to reside or have a Surgery within the District, and to perform the several duties prescribed in the Orders of the Ministry of Health.

Forms of application, which can be obtained from the undersigned by forwarding stamped addressed envelope, must be returned to me by 10 A.M. on 6th April, 1925.

The successful candidate will be required to undergo a medical examination by the Guardians' own Medical Officer.

Canvassing the Guardians will be deemed a disqualification.

By order,

W. H. GLANVILLE, Clerk.

County Borough of Dewsbury.**APPOINTMENT OF MEDICAL OFFICER OF HEALTH.**

The Dewsbury Corporation invite applications from duly qualified and registered Medical Practitioners holding the Diploma of Public Health for the position of Medical Officer of Health at a salary of £900.

The gentleman appointed will be required to devote the whole of his time to the duties of the office, to reside in the Borough, and will not be allowed to engage in private practice. All emoluments or fees which may be payable to, or received by him, will have to be paid over to the Corporation.

The appointment will be made in accordance with the Public Health Officers' Act, 1921, and the Sanitary Officers' Order, 1922, and subject to the terms of the said Order, and to the approval of the Minister of Health.

Canvassing either directly or indirectly is prohibited. Applicants may, if they desire, forward fifteen copies of their application and testimonials for the use of the members of the Committee.

Applications, with copies of not more than three recent testimonials attached, to be sent to me, endorsed "Medical Officer of Health" not later than the 15th April, 1925.

HOLLAND BOOTH, Town Clerk.

Town Hall, Dewsbury, 21st March, 1925.

AMENDED ADVERTISEMENT.**City of Cardiff.****ASSISTANT MEDICAL OFFICERS.**

Applications are invited for the appointment of Assistant Medical Officers (one Male and one Female) under the Health and Education Committees of the Cardiff City Council.

Candidates must have had not less than three years' experience since graduation and must hold a Diploma in Public Health. Other qualifications being equal, special consideration will be given to candidates who have had experience of Orthopaedics and the female candidates with experience in the treatment of Venereal Diseases.

The persons appointed, who will act under the direction of the Medical Officer of Health and School Medical Officer, must devote their whole time to official duties, and reside within the City of Cardiff.

The salary in each case will be £600, rising to £750 per annum by annual increments of £25. The officers appointed will be required to contribute under the Superannuation Scheme of the City Council.

Forms of application and information as to the duties attached to the appointments may be obtained from the undersigned, by whom applications, with copies of three recent testimonials (endorsed "Assistant Medical Officer"), must be received not later than 4th April, 1925.

RALPH M. F. PICKEN,

Medical Officer of Health and School Medical Officer.
City Hall, Cardiff, 16th March, 1925.

Liverpool County Borough.**LOCAL EDUCATION AUTHORITY.****JUNIOR ASSISTANT SCHOOL MEDICAL OFFICERS.**

Applications are invited for three Junior Assistant School Medical Officers in the Department of the Medical Officer to the Local Education Authority at a salary of £600 per annum in each case. Applicants must be registered Medical Practitioners and shall have had at least three years' experience. It is desirable that they should have had some special experience in School Hygiene and in the study of Diseases of Children.

The Officers appointed will be required to devote their whole time to the service of the Education Authority, under the direction of the Medical Officer of Health, who is the Medical Officer to the Education Authority. They will not be allowed to undertake private practice, and will be required to contribute to the Liverpool Corporation Superannuation Scheme as required by the Standing Orders of the City Council.

Applications, stating age, qualifications, &c., together with copies of not more than three recent testimonials, and endorsed "Junior Assistant School Medical Officer," must be delivered at the Office of the Town Clerk, Municipal Buildings, Liverpool, on or before the 7th April, 1925.

Canvassing of members of the Committee or the City Council is strictly prohibited and will be considered a disqualification.
WALTER MOON,

Town Clerk and Clerk to the Local Education Authority.
Municipal Offices, Liverpool, 16th March, 1925.

WEST AFRICAN MEDICAL STAFF

VACANCIES exist at present for MEDICAL OFFICERS in the WEST AFRICAN MEDICAL STAFF. Candidates, who should be British subjects of European parentage and not over 35 years of age, should apply to the Private Secretary (Appointments), the Colonial Office, London, S.W.1. Preference is given to candidates who have had some professional experience since their qualification. Selected candidates are required to attend one of the Schools of Tropical Medicine, the fees for their tuition being defrayed by Government and an allowance being paid during their instruction.

SALARIES.

2. The initial salary of a medical officer is £660 a year, rising by annual increments of £30 to £720. Officers are appointed on probation for three years and then become eligible for confirmation. On confirmation, the salary rises by annual increments of £40 to £960 a year. If an officer remains for three years on £960 a year, he is eligible, if recommended, to be placed on a scale of salary of £1000 a year, rising by annual increments of £50 to £1150 a year, as if he had been appointed a Senior Medical Officer. Officers are required to undergo an approved course of instruction before proceeding to draw salary in excess of £800 a year.

3. In addition to the salary stated a "seniority allowance," which is non-pensionable and drawn only while the officer is in West Africa, is paid after the officer reaches £720 a year. This allowance is at the rate of £72 a year between £720 and £960 and £100 a year between £1000 and £1150.

4. Free furnished quarters are provided by Government or an allowance paid in lieu thereof. Quarters are usually available. An outfit allowance of £60 (or £30 if posted to Sierra Leone) is granted on first appointment. No income tax is at present levied by the Colonial Governments in West Africa.

PENSIONS.

5. The appointments are pensionable, a minimum service of seven years being required to qualify for a pension. An officer may elect to retire on reaching the age of fifty and may be called upon to retire on reaching the age of fifty-five. Medical officers are permitted to retire if they wish with a gratuity of £1000 or £1250 after nine or twelve years' approved service, but receive no pension in that case.

A Medical Officer whose service had been satisfactory would on retirement be qualified for pension at the following rates, assuming that he retired as a Medical Officer or Senior Medical Officer and had not received promotion to one of the higher offices.

After 16 years' service ..	£508
„ 17 years' service ..	£539 15s.
„ 18 years' service ..	£571 10s.
„ 19 years' service ..	£603 5s.
„ 20 years' service ..	£635 0s.
„ 21 years' service ..	£666 15s.
„ 22 years' service ..	£698 10s.
„ 23 years' service ..	£730 5s.
„ 24 years' service ..	£762 0s.
„ 25 years' service ..	£793 15s.

Alternatively an officer may elect to receive a gratuity of one year's pensionable emoluments (£1270 in the case here considered) and a pension reduced by one-fifth. If the retiring officer had been promoted to one of the higher posts and retired from that his pension would be of greater amount. The maximum pension which can be drawn is two-thirds of the salary (including an allowance for free quarters) at the date of retirement.

6. A contributory scheme for providing pensions for the widows and children of deceased officers has been introduced, and all officers whether married or single are required to contribute to it.

PASSAGES AND LEAVE.

7. Free ocean passages are provided on appointment and when going on leave and returning from leave. Half salary only is paid on the outward voyage on first appointment.

8. After a tour of from twelve and eighteen months' residential service in West Africa, an officer may be granted leave with full salary for the period of both voyages and for one week in respect of each complete month's residence. Married officers who have obtained permission to bring their wives to West Africa may be paid a grant equal to half the cost of their wives' passages out and homewards.

HIGHER APPOINTMENTS.

9. The higher posts in the West African Medical Staff are at present as follows:—

- 20 Senior Medical Officers (£1000 to £1150 plus £100);
- 9 Assistant Directors Medical Service (£1300 plus £260 duty allowance);
- 2 Deputy Directors Medical Service (one at £1400 a year plus £280 duty allowance; one at £1500 a year plus £300 duty allowance);
- 3 Directors Medical and Sanitary Service (one at £1800 a year plus £360 duty allowance, one at £1600 a year plus £320 duty allowance, one at £1400 a year plus £280 duty allowance).

A duty allowance is non-pensionable, and is drawn only while the officer is resident in the Colony.

10. In addition, there are at present six Senior Sanitary Officers (£1050 to £1200 plus £210 duty allowance), three Deputy Directors Sanitary Service (one at £1500 a year plus £300 duty allowance, two at £1300 a year plus £260 duty allowance), and one Assistant Director Sanitary Service (£1300 a year plus £260 duty allowance). Officers holding these appointments are required to possess a qualification in Public Health. There are also a certain number of Specialist appointments (£1300 plus £260 duty allowance rising after five years to £1400 plus £280 duty allowance), and appointments as Medical Officers of Health which carry a special addition to salary.

GENERAL.

11. The West African Medical Staff serves the Colonies and Protectorates of Nigeria, the Gold Coast, Sierra Leone, and the Gambia. Officers are appointed to the Staff and are liable for service under any of the four administrations, though transfers from one to another are not usually made except on promotion or in case of emergency.

12. Private practice is allowed to Medical Officers and Senior Medical Officers, but the privilege may be withdrawn by the Governor should he consider it desirable. In most stations there is little opportunity for such practice, and as a general rule stations where private practice can be found are allocated to the more senior members of the Staff.

13. Further particulars may be obtained from the Private Secretary (Appointments), Colonial Office.

The Hospital for Sick Children,

Newcastle-upon-Tyne.—The Committee of Management invite applications for the post of HONORARY PHYSICIAN to the Electrical Department. Applications, stating age and qualifications, with copies of testimonials, should be sent to the Secretary, Mr. Neil Brodie, 18, City-road, Newcastle, on or before 11th April, 1925. N. L. FLEMING, Town Clerk.

Town Hall, Bradford, 23rd March, 1925.

The Royal Infirmary, Sheffield.

The Weekly Board of Management invite applications for the post of HOUSE SURGEON.

The salary attached to the appointment is £80 per annum, with board and residence.

Applications, with copies of testimonials, to be addressed to JNO. W. BARNES, Secretary. Board Room, 24th March, 1925.

Hull and Goole Port Sanitary AUTHORITY.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

The Hull and Goole Port Sanitary Authority invite applications for the appointment of Assistant Medical Officer of Health, to carry out under the direction and supervision of the Medical Officer of Health, the routine work of Port Sanitary Administration, the Medical Inspection of Aliens, Bacteriological work and such other duties as he may be called upon to perform.

Applicants to be under forty years of age, and must hold a registered degree or diploma in Public Health or State Medicine. The person appointed will be required to devote the whole of his time to the duties of the office, and also to contribute at the rate of 5 per cent. of his salary to a superannuation fund under the Local Government and Other Officers' Superannuation Act, 1922.

Salary £750 per annum.

Applications, stating age, qualifications, experience, and present occupation, to be sent to me, with copies of three testimonials of recent date, on or before Tuesday, the 31st day of March, 1925, marked "Assistant Medical Officer."

H. A. LEAROYD, Clerk to the Authority.

Guildhall, Hull, 17th March, 1925.

University of the Witwatersrand, JOHANNESBURG.

SENIOR LECTURER IN DENTAL ANATOMY, PHYSIOLOGY AND HISTOLOGY

Applications are invited for the above post, which is full-time, from qualified and registered Dental Practitioners.

SALARY £450 per annum, rising by annual increments of £25 to £650 per annum, plus relative local allowance. On a salary of £450 per annum this at present amounts to £64 per annum. Half salary during voyage to South Africa.

DUTIES The appointee will be ex officio a member of the Senior Honorary Visiting Staff of the Witwatersrand University Dental Clinic, with duty during one forenoon per week at that Institution. In the first instance for two years, with a prospect of renewal.

ENGAGEMENT Duty commences on 1st July, 1925, or as soon thereafter as possible.

TRANSPORT £40 will be allowed towards the cost of the voyage subject to a proportionate refund in the event of resignation within three years.

Applications, with copies of testimonials, all in triplicate, should reach the Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar-square, London, W.C. 2 (from whom forms of application and further particulars may be obtained), not later than 11th April, 1925.

Applications are invited for the post

of ASSISTANT MEDICAL OFFICER in BRITISH GUIANA. Candidates should be registered Medical Practitioners. Salary £500-£700 by annual increments of £25; but appointment for two years in the first instance. Free bachelor quarters.

Further particulars can be obtained from the Private Secretary (Appointments), Colonial Office, Downing-street, London.

BOVRIL MEDICAL AGENCY, Ltd.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON.

Telephone: GERRARD 3543 (3 Lines).

Established by Bovril, Limited, to provide an efficient and reliable transfer service for the Profession at minimum Charges.

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES, who have both had many years' experience as Medical Transfer Agents.

An Accountant's Certified Report is required in respect of every Practice or Partnership the disposal of which is undertaken by the Agency.

The commission chargeable in respect of any Practice in Great Britain placed exclusively in the hands of the Agency for transfer has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50). In the case of Foreign and Colonial Practices similarly placed the maximum is seventy-five pounds (£75).

NO CHARGE IS MADE TO PRINCIPALS FOR THE INTRODUCTION OF LOCUM TENENS OR ASSISTANTS. Accountancy and Legal Services furnished by the Agency, where desired, at moderate inclusive charges.

PRACTICES AND PARTNERSHIPS FOR SALE.

- 1. SOUTH-WEST OF ENGLAND.—Coast Town.—PARTNERSHIP.**—A share representing nearly £2000 a year is for disposal in a well-established middle-class Practice situated in a very favourite Hospital town. There are various appointments, all transferable, and a panel of about 800. Advice and medicine 3s. 6d., 5s., and 7s. 6d.; visits and medicine 5s. to 21s. Little Midwifery at from 4 to 10 guineas. Well-situated ten-roomed house, on the sea front, in good repair; rent £75 on lease. Premium for share £3000, payable cash.
- 2. NEAR EPPING FOREST.—PARTNERSHIP.**—A one-fifth share (to commence with) is offered in an old-established and rapidly growing middle-class Practice. A further share will be sold after two years. Income approximately £3000, including £850 from panel and £300 from appointments. Advice and medicine usually 3s. and 4s.; visits and medicine 3s. 6d. to 10s. 6d., mostly 5s. and 6s. About 50 cases of Midwifery from 3 to 5 guineas. There is unlimited scope for a man who is keen to develop this Branch of the work. A suitable house will be secured for the incoming partner, on rental. Can be worked with a bicycle. Premium 2 years' purchase, payable cash.
- 3. LONDON, S.W.—Residential Suburb.—PARTNERSHIP.**—Owing to the death of the Senior Partner the Half Share in a very old-established Mixed Better-class Practice is for immediate disposal. Average income nearly £3000. Appointments are worth about £300. The deceased Partner was not on the panel. Fees 3s. 6d. to 10s. 6d. Very little Midwifery. House is a large detached one, standing in its own grounds, with good garden, tennis-court. Price £4000. Premium 1½ years' purchase.
- 4. LONDON, S.W.—A very sound Mixed General PRACTICE.** Income for the last year approximately £1800. Panel of 1500. Advice and medicine 2s. 6d. and 3s. 6d.; visits and medicine 3s. 6d., 5s., and 7s. 6d. House contains reception, 6 bedrooms, professional rooms, &c.; very good garden. Held on lease at £120 a year. Premium 1½ years' purchase.
- 5. IN A GOOD-CLASS RESIDENTIAL SUBURB OF LONDON,** a well-established Mixed General PRACTICE. Average income about £1750. Small panel of 220. Advice and medicine 2s. 6d. to 5s. 6d.; visits 3s. 6d. to 15s. No Midwifery. Convenient semi-detached house, with small garden, on rental at £85 a year. Premium £2600.
- 6. WEST OF ENGLAND.—Favourite Coast Town.—A very old-established and entirely good-class, non-dispensing, and non-panel PRACTICE.** Average receipts over £1500. Practically no Midwifery or night-work. Convenient house; would be let on lease at £100 p.a., or preferably sold. Rapidly growing town and excellent climate. Small Hospital. Premium 1½ years' purchase.
- 7. SOUTH LANCs.—Country Practice.—PARTNERSHIP.**—A One-third Share in a sound unopposed Country Practice, situated in very pleasant surroundings. Income about £4500, with very real and considerable scope. Fees 2s. 6d. to 21s. Suitable house available; on rent at about £50 p.a. Purchaser should be between 30 to 35 years of age, preferably married, and a hard worker. Premium 1½ years' purchase, payable £1500 cash and balance by instalments.
- 8. IN A PLEASANT DISTRICT (Population 7000) WITHIN 20 MILES OF LONDON.**—An old-established PRACTICE worth nearly £1300 a year, including union (£150) and panel of 600. Patients mixed class. Visits 5s. to 7s. 6d. Midwifery 3 to 5 guineas—25 to 30 cases yearly. Small house (large consulting and waiting-rooms, 2 reception-rooms, 3 bedrooms, bathroom, &c.) with garden; rent only £35 a year on lease. Premium £1900. Efficient introduction given. Golf, tennis, cricket, &c. Good educational facilities.
- 9. WITHIN 10 MILES OF VICTORIA.—Outlying Residential Suburb.—PARTNERSHIP.**—A Half Share in an old-established Mixed General Practice. Average income for the last 3 years over £2500. Panel of about 1100. Advice and medicine from 2s. 6d. (cash) and 3s. 6d.; visits and medicine 3s. 6d. to 7s. 6d. Very little Midwifery, from 3 to 5 guineas. Well-built corner house, with 2 reception-rooms, waiting-room, consulting-room and dispensary, 5 bedrooms. Small garden. Held on lease with 70 years to run at a ground rent of £14. Will be sold for £1600 or let on rental. Premium 2 years' purchase.
- 10. SOUTH-WEST OF ENGLAND.—Small Coast Town.—PARTNERSHIP.**—A Three-tenths Share (to commence with) is for disposal in an old-established Practice. Average income over £5500, including various appointments and panel of about 1200. Advice and medicine 3s. 6d. to 10s. 6d.; visits 4s. to 21s. medicine extra. A few Midwiferies at from 2 to 10 guineas. Large detached house, with garden, garage. Held on long lease, with a ground rent of £8 a year. Price £2000, a considerable part of which could be obtained on mortgage. Sport of all kinds, social club, and good educational facilities. Premium 2 years' purchase.
- 11. SOUTH CORNWALL.—PARTNERSHIP.**—A Half Share is for disposal in an old-established Mixed General unopposed Country Practice, situated within a few miles of the Sea and a Hospital Town. Income for the immediate past year £2600. Panel of about 1300. Advice and medicine 3s.; visits and medicine 5s. to 25s. Especially attractive detached house, with 3 reception, 4 bedrooms and dressing-room, bathroom (h. & c.), large garden with 2 lawns, orchard, &c.; rent £75 p.a., or will be sold for £1500. Good schools for boys and girls within reach by motor-bus. Premium £2000 cash, or £2100, part by instalments.
- 12. LONDON, NORTH.—Residential Suburb.—PARTNERSHIP.**—A One-sixth Share (to commence with) in an old-established, non-dispensing Practice is offered to an experienced and well-qualified Englishman or Scotchman, after short preliminary Assistantship. The income is nearly £5000 a year, and increasing. Fees mostly 5s., 7s. 6d., and 10s. 6d. Premium 2 years' purchase on the average for the last 3 years.
- 13. LONDON, NORTH.—Centrally situated.**—An old-established Middle- and Working-class PRACTICE. Steady average income of £1130, including a panel of 1100, capable of much increase. Fees from 2s. 6d.; visits from 3s. 6d. Very little Midwifery. Small house, with 2 reception, 3 bedrooms, professional rooms, &c.; rent £45, on lease. Premium £1800.
- 14. NEW ZEALAND (NORTH ISLAND).**—In an increasing and quite detached Suburb of a large Town, amidst most beautiful scenery of Harbour and Sea, an old-established PRACTICE is for disposal. Held by Vendor 14 years. Cash receipts average over £1500 p.a., including lodges worth about £380. These latter pay 25s. p.a. for single and married members. Population about 6000. Two opponents, one of whom is negligible. Fees 7s. 6d. to 10s. 6d., medicine extra, and up to £2 2s. outside Suburb. Midwifery 4 to 5 guineas, outside suburb 5s. per mile. Good substantial 2-storied house, commanding splendid views, and containing 8 rooms, bathroom, kitchen, garage. Vendor's property. Price £1800, part on mortgage. Premium £1200. Scope for both Private and Surgical work.

Profits accruing to Bovril, Ltd., from the Agency will be allocated amongst recognised Medical Charities
Full Schedule of Terms and Conditions will be forwarded on application.

FELLOWS MEDICAL MANUFACTURING CO., Inc.
26 Christopher Street, New York City, U. S. A.

A fine product from the laboratories of E. SCHERING.

VERAMON
TRADE MARK.

Frequently in everyday practice the physician, being confronted with the choice between morphine (or other habit-forming drug) and unrelieved pain, wisely prefers the latter. Here the new analgesic, Veramon, is a friend alike to the physician and the patient. This preparation is a chemical compound of Barbitone and Amidopyrin, on Burgi's drug combination principle, whereby the analgetic effects of both components are enhanced, while the hypnotic effect is almost entirely eliminated. **It is safe and non-habit forming.** Veramon is next only to morphia in pain-relieving properties, and its exhibition is unaccompanied by any associated ill-effect.

Original Packages—TABLETS: In tubes of 10 × 6 grs.
POWDER: In boxes of 1 oz.

Samples and literature on request from the Importers:

A. & M. ZIMMERMANN, LTD., 3, Lloyd's Avenue, London, E.C.3

For Atophan announcement see page II. Cover.

BYNIN Amara

"A Distinct Advance on Easton's Syrup."

—The 'Lancet.'

'Bynin' Amara is an analogue of the well-known Easton's Syrup, but it is therapeutically much superior to that preparation. The syrup is replaced by 'Bynin,' pure active Liquid Malt, which affords a far better vehicle than the former, as it is actively digestive and nutritive. An added advantage is that the nauseous flavour of Easton's Syrup is effectively masked, whilst there is no possibility of sugar crystallising out and carrying down with it the active alkaloidal principles.

DOSE FOR ADULTS—A dessertspoonful to a tablespoonful in twice the quantity of water twice or on occasion three times daily.

Further particulars and free sample will be sent on request.

Allen & Hanburys Ltd.
37 Lombard Street, LONDON, E.C. 3.

Composition

Quinine	grains
Phosphate	1½
Iron Phosphate	2
Nux Vomica	
Alkaloids	
equal to Strychnine	
Phosphate	1/8
